of the copper or because of insufficient stirring and mixing, and much of the trouble experienced by foundries in the use of copper has doubtless come from inadequate mixing. In the case of poorly mixed No. 12 alloy made by adding copper to aluminum it is not unusual to find the first pour running 3 to 5 per cent copper and the last pour 9 to 11 per cent copper. It takes a longer time to dissolve copper in aluminum than it does to dissolve the rich alloys, principally because of the difference in the melting points; viz., aluminum, 658.7 deg. C.; copper, 1,083 deg. C.; 33:67 copper:aluminum alloy, 540 deg. C.; and 50:50 copper:aluminum alloy, 575 deg. C. Metals which form solutions in the liquid state and in whole or in part in the solid state are more easily alloyed the less the difference in melting points.

As to the possible saving in cost made by using copper instead of a rich alloy, this may be offset by the greater expense incurred in dissolving the copper, and it may be further offset by comparative figures on casting losses, and also dross losses.

USE OF 33:67 Cu:Al ALLOY

An alloy containing 33 per cent copper and 67 per cent aluminum is employed in some foundries, but it is less widely employed than either pure copper or 50:50 copper:aluminum for the manufacture of No. 12 alloy. The alloy in question has the minimum melting point of the binary system, and shows a typical eutectic structure; it melts at about 540 deg. C. (1,004 deg. F.). The 33:67 alloy does not segregate within itself as does 50:50 copper:aluminum, and this is an advantage, pointed out by foundries who use the former for introducing copper into aluminum. As is well known, when a eutectic alloy freezes the crystallization of both components takes place simultaneously, and thus forms a very intimate mixture. Such an alloy cannot properly be considered as homogeneous, but the intimate mixture might approach homogeneity. The low melting point of the 33:67 alloy is also of advantage, for if placed in liquid aluminum it quickly alloys, since it is melted almost immediately. If charged solid together with solid aluminum it will melt first, but there will be some diffusion of the solid aluminum into the liquid alloy before the former melts. In foundry practice 33:67 copper:aluminum alloy, aluminum ingot and foundry scrap are charged in the proper proportions so as to produce No. 12 alloy, and the relative amounts of each material used in a charge may vary considerably.

The main disadvantage in making and using the 33:67 alloy lies in the fact that so much aluminum must be melted in preparing it, and larger quantities of the alloy must be remelted in manufacturing No. 12 alloy. The objection is also offered that it is not so easy to calculate the make-up of charges when using this rich alloy. This is not a serious objection, but the former disadvantage is. However, it has been shown to be a satisfactory rich alloy, from the metallurgical standpoint, for introducing copper into aluminum.

USE OF 50:50 Cu:Al ALLOY

The majority of the foundries in the United States favor the use of the 50:50 copper:aluminum alloy for introducing copper into aluminum. This alloy melts at 575 deg. C., but it is liable to be badly segregated unless thoroughly stirred during its preparation and then frozen rapidly by casting into chill molds. If segregated it may cause some non-uniformity in suc-

¹R. J. Anderson, "Diffusion of Solid Copper in Liquid Aluminum," *CHIM. & MET. ENG.*, vol. 23, No. 12, p. 575 (Sept. 22, 1920).

cessive heats of No. 12 alloy, but ordinarily no trouble should occur from this source. Due to the fact that the 50:50 alloy melts at a lower temperature than aluminum, it will readily alloy. The objections offered to both the rich alloys include the cost of making the alloys and the liability that weighing mistakes may be made in the melting room. In using 50:50 copper:aluminum the requisite amounts of the alloy and aluminum ingot plus No. 12 scrap are charged together.

It has been pointed out when discussing the use of copper directly in making up No. 12 alloy that the heats may run "hard" and "soft" because of failure to stir thoroughly. Even with the use of the rich alloys vigorous stirring is essential if castings of uniform composition are to be produced.

COMPARISON OF THE METHODS

In comparing the above methods from the practical standpoint the foundryman is interested in knowing (1) which method is the more economical, (2) which method is the more easily carried out in the foundry, and (3) which method gives the better castings. The tentative answers to these questions, as they appear to the writer, will be given after comparing the different methods in detail.

With regard to the use of copper, the main advantages claimed by foundries which employ that method are that there is less liability for error in weighing charges than when a rich alloy is used, and that the cost of preparing rich alloys is saved. The presumed former advantage appears to be untenable because, once the charges are calculated, weighing out definite amounts of metal is simple and can be done by very low-grade labor. The more apparent advantage, if it is one, should arise in reduced production cost brought about by the saving in cost of making a rich alloy. That advantage may be partially offset in some foundries because, in alloying copper with aluminum directly, the cycle will generally require a longer melting period. However, unless the proper relation between molding and melting is worked out the melting may be in advance of the molding, so that the charges might thereby be heated longer than actually necessary. The best practice would insure that the condition be reversed, and that the molding should always be in advance of the melting; in this way the heats would be poured as soon as ready.

There appears to be some difficulty at times in obtaining a supply of sheet copper suitable for the purpose in question, and less desirable forms of copper might have to be used with attendant disadvantages. The situation in regard to that matter may be largely dependent upon local conditions and periodic conditions in the copper scrap market. Scrap copper is available in the following forms: Heavy copper, consisting of copper not less than $\frac{1}{8}$ in. thick (including heavy wire, clippings and punchings, and segments), No. 1 and No. 2 copper wire, and light copper (including fabricated copper and sheet). If foundries have difficulty in alloying solid copper with liquid aluminum the trouble lies in the use of too large pieces of copper, too little stirring, or too low temperatures. Of course, it is conceded that in ordinary melting practice the temperature should be kept low, say about 750 deg. C. or so; where the castings must be poured at higher temperatures, because of difficulty in running them, the furnace charges must be heated to 800 or 850 deg. C. However,

at both low and high temperatures solid copper alloys readily with aluminum if the pieces of copper are small and light.

One metallurgist in the light alloy industry has written to the author on the subject as follows: "Under usual working conditions—i.e., with the class of labor available, etc.—I do not believe it is possible to use pure copper. In the first place, I do not believe that a uniform product can be produced. Only the other day a case came to my attention where, a few years ago, a foundry went through a period of considerable trouble with its castings. For some reason it took this foundry a long time to discover why the castings were running hard and soft. The company making them was trying to alloy copper directly."

There is this to be said with regard to the use of copper: The tendency on the part of melters is to raise the heats to unduly high temperatures to hasten alloying, and further there is danger in not thoroughly stirring the melts. The writer's experience has been that copper may be used to advantage under certain definite conditions, and in fact it will be just as satisfactory in some cases as a rich alloy if proper attention is given to details. Metallurgically, it is generally recognized as poor practice to attempt to alloy metals of greatly different melting points directly in commercial work. In the case of aluminum:copper alloys the difference in melting points between copper and aluminum is 425 deg. C. In alloying the two metals by the addition of solid copper to liquid aluminum advantage is taken of solution and diffusion in the solid state, but normally the temperature may have to be raised somewhat above that necessary when using either of the rich alloys.

The use of a rich alloy, usually 50:50 copper:aluminum, is an old practice. In manufacturing light alloys in the foundry there are definite advantages in its use. There is no evidence to show that No. 12 alloy made by the use of a rich alloy is any better than when made with copper, but the device of employing a rich alloy is certainly a convenience. This alloy is very brittle, due to the presence of much CuAl , and this property enables the alloy to be broken readily and thus weighed with great accuracy when necessary. Furthermore, it is possible to hold the melting temperatures relatively low, and that is an important point. The 50:50 alloy is much more brittle than the 33:67 alloy, so from the standpoint of brittleness the former is to be preferred. The main objection offered in connection with the use of the 33:67 alloy is that more of it must be used than the other alloy in making No. 12; furthermore, it is not extremely brittle, and it is not so easily calculated.

CONCLUSION

It appears, taking everything into consideration, that light aluminum:copper casting alloys for casting purposes may be most conveniently made by using the 50:50 alloy. Under the conditions of fast practice which obtain in large foundries this alloy appears to be safer. There is less calculating to be done than in the case of 33:67 alloy; it melts at a lower temperature than aluminum; it is brittle and therefore can be weighed out with great accuracy; and, considering all factors, it is more fool-proof. The use of copper may be more economical in some cases. So far as quality of castings is concerned the various methods are doubtless equally good, provided thorough alloying is obtained.

Proceedings of Rubber Division, A.C.S., Chicago Meeting, 1920

Committee Reports — Aging of Some Rubber Compounds — Microscopic Study of Vulcanized Rubber Containing Fillers — Organic Accelerators — Polysulphide Theory of Accelerator Action — Effect of Heat and Light on Vulcanized Rubber—Symposium on Rubber Analysis

THE convocations of the Rubber Division at the sixtieth meeting of the American Chemical Society in Chicago, Sept. 8 and 9, 1920, were held in Kent Hall, University of Chicago. About one hundred and fifty rubber men attended. In the absence of Dr. LEWIS the vice-chairman, G. D. KRATZ, presided.

REPORTS

Physical Testing: Mr. SIMMONS reported considerable difficulty in obtaining the necessary co-operation from other bodies interested in rubber testing to permit the drawing up of standard methods. The Rubber Division of the American Society for Testing Materials was characterized by several as being quite dormant.

Accelerators: At the previous meeting a resolution aimed to prevent the sale of unknown and harmful accelerators under trade names was passed. The executive committee thought it better to not publish the information but to file it with the secretary, where it would be available for all members of the division. The report was accepted and Messrs. Redford, Tuttle, Zimmerly and the secretary (Mr. Smith) were appointed a committee to put the plan into effect. All advertised accelerators will be listed and their exact composition determined. Information regarding them may be obtained from the secretary.

Literature: For the improvement of the analytical symposium, W. W. EVANS, of the B. F. Goodrich Co., distributed to the members of the division a volume of abstracts from the literature covering all phases of rubber analysis. He went as far back in the files as he could find anything of value attached to the work. The volume is an excellent addition to any rubber man's library. From this came the idea that it would be desirable to issue a volume of abstracts each year, so as to keep the members fully informed on all that has been done. It was pointed out that *Chemical Abstracts* has not the space necessary for longer abstracts. Frequently an important article in a foreign language must be so boiled down that it is practically denatured. Any chemist who might wish to use it will be forced to consult the original. This is not always easy to do. The members present were of the opinion that longer and more comprehensive abstracts could be prepared by themselves and given to one of the American rubber journals for publication. A committee consisting of Messrs. Evans, Hall and Redford was appointed to handle the work during the coming year. Mr. Evans announced that since the vote was unanimous he understood that no one would decline any abstracting he might be asked to do. He also mentioned that at the next meeting a list of delinquent abstractors would be given out.

THE AGING OF SOME RUBBER COMPOUNDS

This paper, by Mr. DEPEW, of the New Jersey Zinc Co. research laboratories, described accelerated age tests

carried on in an oven at 70 deg. C. for periods up to 16 days. Three compounds were chosen:

	A	B	C
First latex crepe	92.0	92.0	92.0
Sulphur	5.5	5.5	5.5
Hexamethylene-tetramine	1.5	1.4	1.4
Zinc oxide	84.0	98.0	22.0
Gas black			25.0
Lithopone		20.0	

Basing aging on decline in tensile strength with time, compound A was shown to be somewhat better than B and much better than C. B and C were worked out to have the same volume relations of filler to rubber. This would apparently indicate that from an aging standpoint it would be better to replace gas black, which is extensively employed with zinc oxide in pneumatic tire treads, by lithopone.

However, in the discussion following this paper it was pointed out by several that doubtless through inexperience the New Jersey Zinc Co. men had used approximately one part too much hexamethylene-tetramine and that the poor results obtained were probably due not to any fault of the black but to a formula not properly balanced with respect to sulphur and accelerator. Also in view of the fact that few rubber men are satisfied with the accelerated age tests as they now stand, it would appear that the conclusion above mentioned must be proved more conclusively.

SOME MICROSECTIONS CUT FROM VULCANIZED RUBBER ARTICLES

The work described in this paper, also by Mr. DEPEW, was largely that of Henry Green and Roger Graver. The New Jersey Zinc Co. laboratories are perhaps further advanced in the application of metallographic methods to rubber than any others in America. In cutting sections of rubber an ordinary Spencer microtome is employed. The sample is frozen first by CO₂ and then by liquid air in a matrix of 90-10 water and glycerine. Liquid air is obtained from the manufacturer in Icy-Hot thermos bottles.

Slides showing the fineness of zinc oxide, aluminum flake, whiting and litharge were exhibited. The following sections were shown:

(a) White tread containing zinc oxide and magnesia as an accelerator. The zinc particles were all dispersed, but a large particle of magnesia was in evidence. The contrast was so great that Mr. Depew referred to it as a "rock."

(b) Red rubber sole. The particles of iron oxide and the fibers introduced for their stiffening action were visible. It was noticed that the particles were arranged in parallel lines following the direction of the grain of the stock.

(c) Gray tread. A white stock containing sufficient lamp black to "gray" it was exhibited. The lamp black was not well dispersed and agglomerates were in evidence. As before, the zinc oxide was well dispersed.

(d) A carbon (gas) black-zinc oxide stock. The

carbon black was found in agglomerates. The zinc oxide was well dispersed.

(e) Another section same as "d." Here both the zinc oxide and the carbon black were well dispersed.

(f) Side wall. Zinc oxide crystals and whiting were seen.

(g) Cushion. This stock contained 1 per cent of zinc oxide and a small amount of reclaim, which was evidenced by dark brown spots.

It was pointed out that by analysis one cannot differentiate blanc fixe from ground barytes. With the microscope this is very readily done. They are planning the use of polarized light for various fillers and staining methods for glue, etc.

In the discussion which followed it was pointed out by Mr. TUTTLE that the heating effect which leads to the disintegration and blowing out of solid tires is enormously increased by poor dispersion—i.e., by the presence of agglomerates.

THE ACTION OF CERTAIN ORGANIC ACCELERATORS IN VULCANIZATION OF RUBBER

The relative activities of molecularly equivalent amounts of aniline and diphenyl-thio-urea in the acceleration of vulcanization were compared in rubber-sulphur mixtures and in mixtures which contained zinc oxide in a paper by G. D. KRATZ, A. H. FLOWER and B. J. SHAPIRO.

In a rubber-sulphur mix the activity of aniline was found to be much greater than that of diphenyl-thio-urea. In mixtures which contained zinc oxide the reverse was true.

With aniline as the accelerator either in the presence or absence of zinc oxide the same maximum tensile strength was obtained, accompanied by a higher sulphur coefficient in the absence of zinc oxide than when this substance was present.

The mixtures which contained zinc oxide attained the same maximum tensile strengths at approximately the same sulphur coefficients, irrespective of whether aniline or diphenyl-thio-urea was employed as the accelerator.

Kratz concludes that from his evidence there is approximately no general relation between the physical properties and sulphur coefficients of accelerated mixtures.

The activities of aniline, methylaniline, dimethylaniline, para- and meta-phenylenediamine, para-toluidine, para-benzidine, phenylhydrazine, and hydrazobenzene were compared in pure gum (8.1 per cent sulphur on the rubber). The accelerators were compounded in hundredth mole quantities. All samples were vulcanized ninety minutes at 148 deg. C. Para-toluidine in the above combination gave the best results (tensile 2,476 lb. per sq.in., 920 per cent elongation).

No definite relation was found to exist between the dissociation constants and the relative activity as accelerators except in the case of closely related series. This may be due to the fact that the substance itself is not the true accelerator, which is some product of its sulphur or other reaction. Thus hexamethylenetetramine reacts with sulphur, giving ammonia, hydrogen sulphide and other reaction products. In such cases dissociation constants are obviously poor indications of relative acceleration. KRATZ regards the NH_2 grouping as of most importance in an accelerator, and finds it advantageous to think of it as a substituted ammonia. Adding a second NH_2 group to the ring does not double the acceleration.

Substances such as aniline hydrochloride, etc., which decompose or react with other components of the mixture to form substances of acid character, do not accelerate unless a neutralizing base (such as zinc oxide) or salt is present.

In common with Van Horn, Kratz regards a preponderance of basicity as essential to acceleration. Thus Girard found that rubber could be vulcanized by heating it in a solution of potassium pentasulphide. The equation probably is:

Kratz has found that ammonium polysulphide and even the hydrosulphide will also vulcanize. With ammonium polysulphide the reaction probably is:

With ammonium hydrosulphide (under pressure) Kratz obtained a coefficient of vulcanization of 4.4; with the polysulphide the value was 1.9.

A THEORY OF ACCELERATION BASED ON THE FORMATION OF POLYSULPHIDES DURING VULCANIZATION

Very few theories of the action of accelerators during vulcanization are to be found in the literature, declared C. W. BEDFORD and WINFIELD SCOTT. Ostromuiskensky considers the activation of sulphur to the formation of thio-ozonides of the type RNH-S-S-S-HNR , which pass sulphur to the rubber, then take up more sulphur, thus repeating the cycle. Dubosc considers it due to the formation of active sulphur by the reaction of sulphur dioxide and hydrogen sulphide. Dubosc seeks to explain the action of aniline by a reaction with sulphur

The authors obtained thio-aniline and hydrogen sulphide, but no acetylene, CS_2 or thiocyanic acid.

Kratz, Flower and Coolidge stated that the activity of aniline was due to a sulphur addition product of aniline such as PhNH_2S , a product which admittedly is probably very unstable.

Taking ammonia as the simplest nitrogen-containing base, it reacts readily with H_2S , forming ammonium sulphide, which in the presence of sulphur is readily converted to the polysulphide $(\text{NH}_4)_2\text{S}_n$ where n may have any value up to 9. Sulphur contained in the polysulphides is more reactive than rhombic or alpha sulphur. Polysulphides as sulphur carriers are quite common in the dye industry and are extensively employed in the manufacture of sulphur colors.

Thus they explain the acceleration of aniline as follows:

True Accelerator

The curing value of para-phenylenediamine they attribute partly to its basicity, but mostly to the fact that at vulcanizing temperature it reacts with sulphur to produce ammonium sulphide along with other basic products.

Aldehyde ammonia liberates large quantities of ammonia during the cure, and at the same time by the action of heat forms strongly basic alkyl pyridine derivatives. Para-nitrosodimethylaniline, which Peachey classes as acidic, reacts with H_2S to give the strongly basic *p*-aminodimethylaniline.

Scott and Bedford class as polysulphide accelerators the phenylene diamines, anhydroformaldehyde-aniline, methylenediphenyldiamine, hexamethylenetetramine, and all others which liberate H_2S or produce it by a reaction with sulphur at ordinary temperatures.

This class of accelerators may be represented as func-

tioning because of the $\begin{array}{c} \text{N}-\text{S}-\text{S}_x \\ | \\ \text{H} \end{array}$ grouping.

The remaining organic accelerators form polysulphides, then the carbo-sulph-hydro group

$\text{N}-\text{C}-\text{SH}$ thus $\text{N}-\text{C}-\text{SH} \text{ S}_x$. This group contains the thiocarbanilides, dithiocarbamates, etc.

The authors in a previous paper explained the formation of thiocarbanilide as follows:

When H_2S , produced by the reaction of rubber resins and sulphur, acts on thiocarbanilide the reaction is reversed, giving the aniline salt of phenyldithiocarbamic acid which, while unstable, is an extremely powerful accelerator.

The dithiocarbamates are the strongest accelerators known and will affect vulcanization at room temperature. Such, for example, is piperidine-piperidyl-dithiocarbamate. If piperidyl (ammonium) polysulphide is added to a rubber cement containing some free sulphur no vulcanization occurs even after a period of two months. In contrast to this a small amount of piperidine was added to a rubber cement containing zinc oxide and sulphur. To this was added a small amount of carbon bisulphide which reacted to form a piperidine-piperidyl-dithiocarbamate. The cement set to a stiff jelly in twenty-four hours.

Inorganic Accelerators: Although H_2S seems to be necessary in a large class of organic accelerators there are cases in inorganic accelerators where it is not required. The sulphides of the alkali and alkaline earth metals readily take up sulphur to form polysulphides.

Zinc oxide and litharge do not form polysulphides. If litharge be added to a solution of yellow ammonium sulphide, lead sulphide is immediately precipitated and colloidal sulphur is liberated from the ammonium polysulphide. In a stock during vulcanization the resins and proteins react with sulphur, liberating ammonia and other basic substances which immediately form polysulphides. The litharge removes H_2S , leaving activated sulphur. Bedford has shown that litharge has very little accelerating effect on deresinated rubber which contains hardly any protein.

The effect of zinc oxide and other bases in increasing the accelerating effect of thiocarbanilide is thought to be due to locking the hydrogen in the tautomeric position attached to the sulphur, thus:

Normal Thiocarbanilide

Tautomeric Form

Summary. All accelerators are thought to fall into two classes:

1. Hydrogen sulphide polysulphide accelerators.

2. Carbo-sulphhydryl polysulphide accelerators.

Discussion. The two papers, that by Kratz, Flower and Shapiro and that of Bedford and Scott, were discussed at the same time.

The remarkable thing is that Kratz, Flower and Shapiro and Bedford and Scott reached the same conclusions but by different routes. These papers are most interesting and instructive.

Bedford pointed out that vulcanization by SO_2 and H_2S as predicted by Dubosc's theory and recently patented by Peabody fits into the polysulphide theory. Thus:

Bedford also mentioned that vulcanization with nitro- or dinitro-benzol in the presence of litharge or caustic is preceded by the formation of a quinoid grouping, thus:

The reaction product of dimethylamine and carbon bisulphide (dimethylamino-dimethyl-dithiocarbamate), which is an extremely powerful accelerator, was reported as unable to effect vulcanization without added sulphur. Zinc oxide is necessary to activate it. The zinc salt of the acid will vulcanize without added zinc oxide.

RUBBER ENERGY

"Rubber Energy" was the title of a paper by W. B. WIEGAND. The energy storage capacity (ft.-lb. per cu.in. when stressed up to the elastic limit) of various materials was compared to that of rubber. Rubber has the enormous value of 14,600 ft.-lb. per cu.in. (as shown by planimeter measurement under the stress strain curve up to the elastic limit). Hickory wood has but 1 per cent of this capacity and spring steel less than 1 per cent. The high energy storage capacity of rubber was recognized early in designing bumpers for railways.

Hysteresis. It is well known that the retraction curve differs markedly from the extension curve. The area under the latter is a measure of the work done in

stretching the test piece—i.e., it represents "input." The area under the former (the retraction curve) represents "output"—i.e., the work given up by the stock. The difference between the areas ("input" minus "output") represents "hysteresis loss." The hysteresis loss of rubber is very high.

Bouasse and Carriere in 1903 found that hysteresis diminished as the number of cycles increased, and finally reached an approximately fixed value. The difference between the first two cycles was found to be greater than that between any other two. Schwartz found in 1910 that the area of the loop became fixed much sooner in a high grade than in a low grade of rubber. He also found that when cycles were generated to a constant final load the increasing extension at the end of each cycle was proportional to the log of the number of the cycle in question. Also these workers found the shorter the extension the narrower was the hysteresis loop.

Another general rule laid down by Bouasse and confirmed by Schwartz is that the greater the speed of generation of the cycle the greater will be its area. You will at once appreciate the significance of this in regard to the internal heating of solid tires. Not only do excessive driving speeds multiply the number of loops per second and therefore the heat limited but they also actually increase the calories of heat generated per revolution of the wheel.

However, the area of the loop diminishes with increased temperature. It is quite fortunate that the reverse is not the case, since our solid tires and breaker strips in our pneumatic casings would go to pieces rapidly but for this compensating law. Incidentally, this temperature relation strongly suggests the resemblance in many respects of rubber to a viscous liquid. In fact, Shedd and Ingersoll use the term "viscosity loop" rather than hysteresis loop for this reason.

Thermal Phenomena. In 1805 Gough recorded that rubber increases in temperature on stretching. This was confirmed by Paige in 1847. Finally Joule also recorded the fact that while metals and other materials cooled on stretching, rubber became warmer. Lord Kelvin applied Le Chatelier's principle of equilibrium and predicted that stretched rubber must contract on heating. Joule confirmed this by experiment and this is now known as the Joule effect. The first stages of extension are accompanied by a slight cooling effect. The corresponding cooling which accompanies retraction of the stretched rubber is definitely less than the heating effect on the extension. This difference, representing the net increase in thermal content of the sample, is the exact equivalent of the hysteresis loop above referred to. This heat must be attributed to internal friction in the rubber.

Comparing the thermodynamical behavior of rubber with better understood systems will be of value. Gases when expanded or compressed isothermally develop pronounced thermal effects. In fact, the energy expended during compression is all turned into heat. Steel springs, on the other hand, are examples of systems which develop practically no thermal effects when deformed. All of the work done on the system appears as potential energy of strain.

Vulcanized rubber is intermediate between a gas and a steel spring. The accompanying figure contains the mechanical conception of rubber. A piston is moved downward by a force W . The rod passes through a friction member which furnishes lost or non-reversible

heat Q_F . The steel spring takes up the potential energy of strain E . The cylinder contains a gas which when compressed gives Q_R , the reversible heat. Rubber is the reverse of this picture. Thus when a piece is stretched we have energy stored up as potential energy of strain.

Heat is given off, part of which is reversible and part irreversible or lost. The search for compounds and cures having Q_F (frictional or lost heat) a minimum is of extreme importance. Returning now to hysteresis. Mr. Wiegand's machine he describes as simple, being actuated by a helical spring which allows him to work at a speed of 20 in. per minute.

He uses a wide test piece and special non-slipping grips. He has found that the area under the third up-curve differs but little from those following. Therefore his test pieces are given two preliminary stretches and are then remeasured and placed in the machine.

The question as to whether he should run to constant load or constant elongation he has not entirely settled yet. Experiments have been made running the loops to from 100 to 500 per cent elongation. He found hysteresis loss (ft.-lb. per cu.in.) when plotted against cyclic elongation enormously increased when past 300 per cent elongation. Therefore he chose 200 per cent elongation and runs all his cycles to this point.

He found that the state of cure has an influence on the hysteresis loss. Cures varying from 50 per cent of the optimum to 275 per cent were made. In general, an undercure showed increased hysteresis, and the minimum loss was obtained with overcured samples. However, taking other considerations such as aging, etc., into account, a cure slightly less than the optimum is desirable.

However, the actual magnitude of hysteresis loss as it varies with state of cure is very low, and consequently ply separation cannot be attributed to it. On the other hand, hysteresis shows a marked linear increase with increase in volume ratio of the active fillers—i.e., those able to store up energy such as gas black and zinc oxide.

It should be pointed out that while carbon black and zinc oxide both give high hysteresis loss the heat conductivity of the former is much less than the latter.

Tests on Tire Sections. To obtain a measure of relative hysteresis losses in tires Wiegand cut 1-in. sections of various tires, clamped one end to a rafter and suspended from the other a long pendulum. By measuring the time necessary for the pendulum to come to a stop he had a measure of the damping effect or the hysteresis loss in the section.

Thus a 3½-in. plain tread stopped in 6 minutes.

Minus the first ply of fabric it stopped in 7½ minutes.

Minus the second ply of fabric it stopped in 8 minutes.

The tread and breaker alone stopped in 21 minutes.

It was found that the hysteresis loss of all the rubber in the section amounted to only that of one ply of fabric. The time of swing of the pendulum was found to fit the equation $T_p = K_1 \times K_2^n$ where n = the number of plies and K_1 and K_2 are constants. The state of cure of the tire was found to be without effect. Mr. Wiegand mentioned that a 5-in. cord tire swings three times as long as the same size in fabric.

The remainder of the paper was practically the same

as that recently published in the *Canadian Chemical Journal* and the *Rubber Age*, except that he showed photomicrographs of the various fillers along with the stress strain curves at different volume relations.

Gas or carbon black he characterizes as the "aristocrat" of fillers, being much superior to zinc oxide and all others. He placed 20 volumes of filler to 100 of rubber as the point beyond which overloading takes place for both zinc oxide and gas black.

Discussion. It was admitted by all that this was a most remarkable contribution and illustrates the aid a physicist can be to the science of rubber technology.

C. O. NORTH illustrated a new type of stress strain curing curve where the loads at various percentages elongation were plotted against time of cure. This method is of particular value in studying accelerated stocks. He also illustrated a corrected stress strain curve where the loads for the various elongations were corrected to the actual cross-section area. It was pointed out that for all stocks examined to date up to 50 per cent elongation and in some cases up to 200 per cent elongation the cure is a straight line—i.e., Hook's law holds. By taking a tangent to the corrected curve at zero the cotangent of the angle of inclination is a measure of the direction or slope of the curve and may be called the true modulus. It is possible that this value may replace the other physical tests in describing the physical properties of a stock.

CONTRIBUTION FROM THE U. S. RUBBER Co. LABORATORIES

The paper by J. F. SCHUEFER on methods for determining free sulphur and antimony tri- and penta-sulphides in golden antimony was withdrawn, and informally substituted by "The Organization of an Information Service in Connection With Industrial Research Organizations" by R. P. ROSE and J. H. REEL.

They stated that in a large corporation 2 per cent of the total turnover may profitably be spent for development, and of this about 2 per cent for information service. A description of the excellent library system of the U. S. company was given.

THE ACTION OF HEAT AND LIGHT ON VULCANIZED RUBBER

JOHN B. TUTTLE presented a paper on "The Action of Heat and Light on Vulcanized Rubber." The action of heat and light on vulcanized rubber is frequently spoken of as being identical, and oxidation is said to be the cause of the deterioration. From published and unpublished tests it is shown that the action of heat is one of change in the rate of the chemical reaction between rubber and sulphur and goes on throughout the entire mass, whereas the action of light is one of oxidation, taking place on the surface. Heat produces no change in the solubility of the rubber substance in solvents such as acetone and alcohol, whereas light breaks up the rubber molecule, forming decomposition products which are readily soluble in acetone.

Peachey Process of Vulcanization. Samples prepared by Mr. Dales of the B. F. Goodrich Co. and by Mr. Kratz of the Falls Rubber Co. were exhibited. Very nice thin sheets were secured by passing H₂S and SO₂ into dilute xylol solutions of rubber, combining them quickly and pouring on a glass plate. All attempts to vulcanize sheets of rubber by hanging first in one gas and then in the other resulted in surface cure only.

Contrary to Peachey's claim, sheets prepared by pour-

ing treated cement on a plate do contain free sulphur which is about as much as is combined.

It was the consensus that the Peachey process is at present of theoretical interest only. Those who have investigated it closely are not nearly as enthused with the idea as some foreign papers would have us believe the English are.

SYMPOSIUM, THE ANALYSIS OF RUBBER

This symposium was led by W. W. EVANS.

The Tetrabromide Method: H. L. FISHER. The various methods were discussed. It was pointed out that in the Lewis method about five times as much potassium iodide should be used as called for. Mr. Fisher was unable to obtain checks with any tetrabromide method and was particularly unfortunate with the Lewis method.

Nitrosite Method: A. H. SMITH. To summarize Mr. Smith's remarks, he finds the nitrosite method more accurate than the tetrabromide, but it is not sufficiently satisfactory for routine.

Alcohol Soda Extract: H. E. SIMMONS. The fineness of the sample is of great importance. The results obtained are of qualitative interest only. This statement also applies to the chloroform extract.

Free and Total Sulphur: J. B. TUTTLE. The sulphur in stocks may be classified as

Sulphur added—free or combined.

Sulphur in reclaim.

Sulphur in organic fillers—oil substitutes, M. R.

Sulphur in inorganic fillers—sulphides, PbS, ZnS, Sb₂S₃, Sb₂S₅, etc.; sulphates, BaSO₄, CaSO₄, PbSO₄; sulphites (in lead sulphate).

Sulphur in accelerators (thiocarbonyl, etc.).

Influencing the determination—PbCO₃, BaCO₃.

Decomposition of the rubber (a) Solution (Carbon); (b) fusion.

The objection to nitric acid is that the fumes carry off some of the free sulphur, thus giving low results when the sulphur is high, as in a cushion stock. Tuttle recommends a combination of fusion and solution methods. Fusion with an alkali is necessary to decompose such materials as BaSO₄.

Do not evaporate down the solution from fusion. Keep it at 400 c.c. and the SiO₂ will not come out. Also do not blast the BaSO₄ precipitate. A Meker burner is satisfactory.

In determining free sulphur, bromine water as per Bureau of Standards method is giving good results.

The Parr calorimeter using Na₂O and the oxygen bomb for total sulphur were discussed. Satisfactory results in some instances were recorded.

Determination of Fillers: H. B. UNDERWOOD. Mr. Underwood found no solution method satisfactory. He prefers to use the ash method with suitable corrections.

During the discussion it was mentioned that the xylol-naphthalene method was perhaps the most satisfactory.

ELECTION OF OFFICERS

The following men were elected for the coming year: Chairman, W. W. Evans, B. F. Goodrich Co.; vice-chairman, C. W. Sanderson, Fisk Rubber Co.; secretary, A. H. Smith, Goodyear Tire & Rubber Co.; executive committee, G. D. Kratz, Falls Rubber Co.; J. B. Tuttle, consulting engineer, New York; C. W. Bedford, Goodyear Tire & Rubber Co.; H. E. Simmons, Akron University; J. R. MacGregor, Eagle Picher Lead Co.

Chemical Industries Likely to Lose Natural Gas Supply

BY R. S. MCBRIDE*

THERE is a great prospect that chemical industries, among others, will have their natural gas supply cut off in certain important districts during the coming winter and it appears unlikely that these supplies will ever again be restored for these industrial uses. The indications of such drastic action on the part of the several state public service commissions having jurisdiction point to these conclusions definitely.

In the tri-state district of West Virginia, Pennsylvania and Ohio, where 70 per cent of the natural gas of the United States is produced and used, the state commissions have been co-operating, together with the commissions of Maryland and New York State, in the consideration of regulations regarding the conservation of gas. It is expected that these commissions will concur in and adopt the several resolutions which were proposed by the national committee on natural gas conservation which worked under the auspices of the Department of the Interior. A report of this committee dated June 11 recommends careful attention to the question of how industrial gas supplies may be curtailed in order to give adequate supply for the domestic users. The importance of this movement to chemical industries is obvious, for among those activities which will receive first attention are the ceramic manufactories, brick kilns, glass factories, carbon-black plants and others which are using natural gas in large quantities.

These five public service commissions have met several times already in conference. They met again on Sept. 10 to decide important policies, and the action above indicated is likely to result from their deliberations. Certainly the Pennsylvania commission gives clear intimation that this will be its findings unless new facts are developed.

U. I. D.

FIG. 1.

Diagram showing the quantity and value of natural gas consumed in the U. S. from 1906 to 1918. The first bar shows at the bottom the per cent of industrial gas and at the top the per cent of domestic fuel consumed. The second bar shows in the same order the value of industrial gas and of domestic fuel consumed.

FIG. 2. DECLINE IN WEST VIRGINIA NATURAL GAS USED IN STEEL MAKING BY THE U. S. STEEL CORP. Based on statistics filed with the West Virginia State Board of Public Works. The number of acres per well has declined from 13.3 in 1911 to 11.2 in 1919. The volume of gas removed has declined from 13.3 billion cu ft in 1911 to 11.2 billion cu ft in 1919. During the same time the number of producing wells has increased from 239 to 371.

The proportion of gas used for industrial and domestic consumers is shown in Fig. 1. (Prepared by E. G. Sievers, U. S. Geological Survey.)

It should be noted that the total quantity of gas available for sale is now decreasing; and this decrease must be borne almost altogether by the industries, since as a matter of general policy it seems widely recognized that the domestic use is of superior importance in a community as a whole, and must be given priority. One of the indications that this effect is already noted is shown in Fig. 2, which was presented by Samuel S. Wyer in his report dated July 7 on the gas situation of the Philadelphia Co. of Pittsburgh. This chart shows the very striking decline in the quantity of natural gas used by the United States Steel Corporation for steel making.

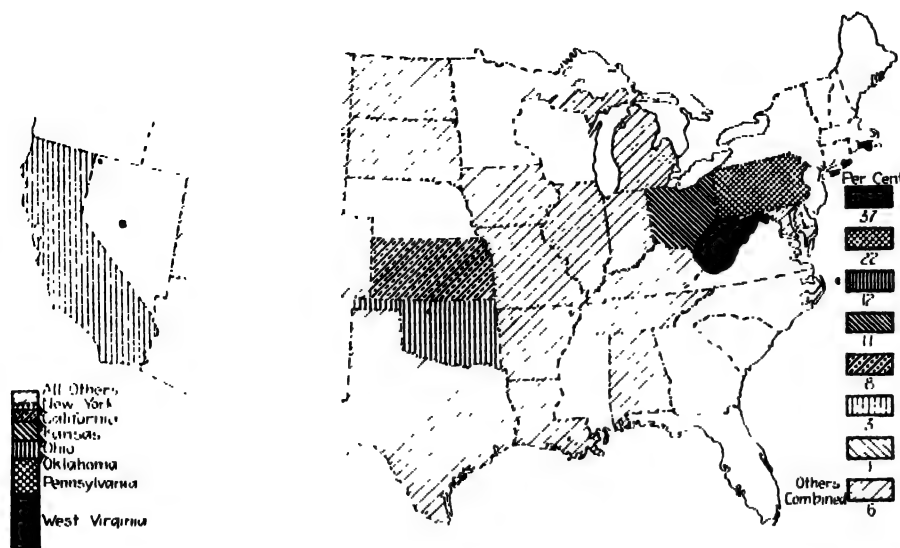

FIG. 3.

Map of United States, showing by states the percentage of natural gas produced from 1906 to 1918.

Fig. 3 (prepared by E. G. Sievers, of the U. S. Geological Survey) shows the dominating importance of the district in question, for, as indicated above, the three states, Pennsylvania, Ohio and West Virginia, jointly represent 70 per cent of the natural gas production of the United States. Moreover, it is to be expected that any conclusions reached with respect to this particular

FIG. 4. DECLINE IN NATURAL GAS CONSUMED IN WEST VIRGINIA

Based on statistics compiled by the United States Geological Survey. The domestic gas per domestic consumer has declined from 188 "M" per annum in 1906 to 165 "M" in 1918, or a decline of 12 per cent. During the same period the industrial gas per domestic consumer has declined from 932 "M" per annum to 689 "M" per annum, or a decline of 26 per cent, and the total gas per domestic consumer has declined from 1,120 "M" in 1906 to 854 "M" in 1918, or a decline of 23 per cent.

territory will also be adopted by the southwestern gas districts of Oklahoma, Kansas and Missouri, where the next largest proportion of gas production, 20 per cent of the total in the United States, is found.

That some curtailment of the industrial supply is to be expected seems certain. Naturally, use of gas under steam boilers will be one of the first uses attacked. This, however, will not be sufficient to accomplish the necessary improvement in domestic supply, and, as above indicated, the ceramic, glass making, carbon-black and related industries will doubtless be next in order for attention.

However, these industries are in a number of cases confronted with the necessity for use of a gaseous sulphur-free fuel, and where these particular uses can be demonstrated conclusively it is likely that the supplies will not be cut off until much more serious shortage is met. For example, certain of the glass-making processes, particularly flattening and annealing of plate glass, are accomplished with great difficulty when using any other fuel. A fuel containing sulphur is particularly objectionable because of the spotting effect on the plate glass. It seems important, therefore, that industries concerned in this problem should carefully analyze their needs and be prepared to present to the state commissions in due time their claims for special attention where these particular demands justify continuance of supply when other parts of the industries cannot be so favored.

France's Foreign Trade for First Seven Months of Year

French foreign trade continues to disclose the desired recuperation in the volume of exports, as compared with the imports, though the adverse balance remains formidable—more than 9 billion francs for the first seven months of the year. During this period, compared with the same period of 1919, there was an improvement of more than 7 billions in the exportations, the importations increasing nearly 3 billions at the same time. The gradual and sure increase in the amount of manufactured goods exported is an encouraging feature. This item shows an improvement of 4,603,984,000 francs over 1919.

The official figures in francs of imports and exports for the first seven months of 1920 and 1919 are as follows:

	Seven Months 1920	Seven Months 1919
Imports:		
Articles of food.....	5,395,180,000	5,706,445,000
Raw materials.....	10,153,394,000	7,369,082,000
Manufactured articles.....	6,212,168,000	5,946,713,000
Totals.....	21,760,742,000	19,022,240,000
Exports:		
Articles of food.....	1,088,721,000	528,315,000
Raw materials.....	2,775,208,000	763,235,000
Manufactured articles.....	7,594,169,000	2,890,185,000
Postal parcels.....	548,532,000	492,667,000
Totals.....	12,006,630,000	4,778,402,000

Segregation in Bars for Steel Tubing

BY HAROLD D. NEWELL

FROM a large number of analyses collected and tabulated it is shown to be by no means unusual, in bad cases of segregation, to find a difference of 50 per cent or more in the percentage of the impurities (sulphur, phosphorus, silicon, manganese, etc.) in the same steel ingot or bar designed for boiler tubing. Such examples of segregation are ordinarily associated with high analysis of original impurities and high temperature of the casting. An example of such an analysis is:

	Sulphur	Phosphorus	Manganese	Carbon
Top of ingot....	0.085	0.033	0.51	0.24
Bottom of ingot	0.032	0.019	0.47	0.15

This undue segregation has been prevented somewhat by allowing the metal to cool to the desired

FIG. 1. SULPHUR PRINT SHOWING EXCESSIVE SEGREGATION OF FeS AND MnS

pouring temperature in the ladle, forming a skull of bad steel and slag on top of the heat, and pouring from under this skull. Steel makers, however, object to this practice, as it is expensive, the skull having to be put aside, broken up and remelted as scrap.

Provided care be taken in manufacture and the pouring be kept well under control, although there will always be some segregation, it should not be a serious matter in a good quality steel. It always occurs in rail steels to a greater extent than is desirable. It is advisable to keep the percentage of impurities in the ladle analysis as low as possible, because the proportion in which the segregating body is present will largely affect the result.

Casting of steel in large quantities undoubtedly favors unequal segregation or distribution; therefore, there will ordinarily be less segregation in a small ingot, especially if it sets and cools much faster than a large one. The rapid cooling on the outside of the ingot prevents segregation there, but the center, remaining fluid for a considerable time, allows the less soluble impurities to travel toward the center. Insoluble impurities, being specifically lighter than the steel, tend at

FIG. 2. SHEARED BAR SHOWING NO SEGREGATION

the same time to rise to the top of the ingot so that in the bottom center there will be less segregation than in the top center. Heavy cropping evidently is necessary to produce quality steel.

The author has been conducting a number of examinations for segregation in acid and basic steel ingots for boiler-tube steel with and without the additions of aluminum in the ladle. It has been concluded as a result that, in ingots to which no aluminum has been added, excessive segregation usually occurs down the central part of the ingot anywhere from 6 in. from the top to half-way down the entire ingot, sulphur tending to segregate the most, then phosphorus, carbon, and finally manganese. The effect of the addition of aluminum in the ladles as an oxidizing agent is to tend to reduce immediately the amount and depth of segregation.

FIG. 3. SULPHUR SEGREGATION IN 3-IN. BAR FROM A BOTTOM-POURED BASIC OPEN-HEARTH INGOT

As is well known, steel tapped from the open hearth is usually more or less oxidized and contains a greater or less amount of iron oxide, which diminishes both its fluidity and strength. As this oxidized metal cools the oxide is partly reduced by carbon with the evolution of carbon monoxide gas, causing more or less violent ebullition and producing steel containing the well-known blowholes. Addition of small amounts of aluminum to such metal greatly facilitates the flow of metal from the ladle and also stops the violent evolution of gases, allowing the production of sound ingots without excessive blowholes. Two to five ounces of metallic aluminum per ton of metal is usually sufficient.

By suitable additions of aluminum blowholes, though always present, may be so reduced that finished material may be relied upon for our purposes. In most cases the blowholes weld up or are reduced

cracks develop which may even extend through the wall of the pierced billet.

Slag inclusions and dirty steel are also the cause of many rejections, as they produce tears and seams. Low-sulphur, bottom-poured basic open-hearth is always preferable for the manufacture of seamless boiler tubing. An example of what may be had is given in Fig. 2, which may be compared with Fig. 1.

Sulphur printing, using ordinary photographic paper, is a good way to keep tab on the sulphur segregation. Such prints showing excessive segregation of manganese and ferrous sulphide taken from rolled 3-in. rounds are given in Figs. 3 and 4. Ladle analyses for both cases conform with the above chemical specifications.

Pittsburgh Seamless Tube Co.,
Denver Falls, Pa.

FIG. 1. SEGREGATION IN 3-IN. ROUND; ROLLED FROM A TOP-POURED SQUARE INGOT

to a minute size in the process of rolling. If this were not the case in carefully made steel, the production of sound tubes of thin gage would be impossible.

SULPHUR SEGREGATION IN STEEL FOR BOILER TUBING

Segregation of sulphur is the cause of considerable trouble in the manufacture of seamless boiler tubing. The usual chemical specifications are:

	Per Cent		Per Cent
C	0.10 to 0.15	S	under 0.035
Mn	0.35 to 0.55	P	under 0.030

A heat containing over 0.035 per cent sulphur usually causes trouble at the piercing mill because of the tendency toward red-shortness in hot-working.

The segregated ferrous and manganese sulphides are thought to become semi-fluid at the working temperature of the furnace, thus lessening the cohesion between the grains of the metal. Because of the unequal strain set up in the solid nearly sulphur-free shell (Fig. 1) and the semi-fluid mass comprising the hot axis of the bar under the piercing operation, inside seams and

Condition of the Belgian Soap Industry

Soft soap is manufactured in practically every important Belgian center and while the factories are usually small there are several larger establishments which have entered foreign markets. Hard household soaps are produced mainly at Brussels, Verviers, Antwerp and Mons and are supplied in cakes, in blocks of all weights, in double bricks, and in yellow, brown, or marble color. Most of this production is used by home demand. Particularly at Verviers some soap manufacturers specialize in pure neutral soap which is used in the linen industry for glossing yarns and fulling fabrics. Toilet soaps are manufactured chiefly at Brussels, Liège, Verviers, Waterloo, Mons, Wavre and Tirlemont. Although importations are still large, the native article shows a tendency to replace the imported toilet soap. Soap powder, for household and industrial use, is a fairly recent innovation in Belgian factories and is almost exclusively made at Brussels, Verviers, Mons and Peruwelz. Medicinal soaps and specialties, such as transparent glycerine, tar, borax, floating bath, sand, pumice and beef-gall soaps, are also manufactured in Belgium.

PRODUCTION OF SOAP

The following statistics give the comparative soap production in Belgium before and since the war:

Kind	1913 Kilos.	1919 Kilos.	Jan. Mar. 1920 Kilos.
Soft soap	17,000,000	3,903,000	2,092,000
Hard soap	6,700,000	5,561,000	2,680,000
Toilet soap	1,750,000	667,500	300,500
Soap powder	2,700,000	2,063,000	1,174,050

Many damaged soap factories were unable to begin work before March, 1919, and, aside from the shortage of raw materials, they met with active competition from American, French and British importers. During 1920 the demand has been most active for hard and powdered soaps, the producers of which were in a fair way to double their 1913 output until general market conditions cut off the demand.

Steps to Raise the Price of Rubber

A recent report from London states that, to raise the price of raw rubber, drastic steps are contemplated by the Rubber Growers' Association, which represents about one-third of the owners of 3,000,000 acres of rubber plantations. The association suggests to members that they so reduce tapplings of rubber trees as to effect a reduction of 25 per cent in the output.

Metallurgical Industry in Belgium

THE Belgian metallurgical industry before, during and after the war is outlined by Emile Trasenster in the May 15, 1920, issue of *Revue Universelle des Mines*, pp. 271-320. The following is a succinct abstract:

The iron and coke industry during 1913 employed 39,500 workmen, and the coal industry 145,600 miners. There were forty-one coke plants with 2,898 coke ovens, producing 3,523,000 tons of coke, requiring 4,601,750 tons of coal, of which 39 per cent was imported. The

other country in the world reached such a high percentage of export; the United States, France, Germany and Great Britain exporting for the same year respectively 5, 13, 30 and 44 per cent.

The iron and steel industry, relying as it did on exporting more than four-fifths of the entire production, had to put up a hard struggle against competition, especially when it is considered that the competitors (Germany, France, United States) had their own iron ores, whereas Belgium had to import, as stated above, more than 99.5 per cent of the ore it needed. This was

AT LEFT A BLAST FURNACE IN 1917, AT RIGHT THE SAME BLAST FURNACE NOV. 20, 1918

consumption of fuel has increased in ten years from 20,228,000 tons in 1904 to 26,046,000 tons in 1913, whereas the production has remained practically stationary (22,761,000 tons in 1904 and 22,842,000 tons in 1913). During 1913, 8,856,153 tons of coal and 1,128,000 tons of coke were imported, as against 4,981,480 tons of coal and 1,002,000 tons of coke exported.

The fifty-four blast furnaces in operation produced 2,484,690 tons of pig iron, requiring 2,662,680 tons of coke, of which 24 per cent was imported, and 6,860,130 tons of iron ore, of which 84,900 tons—i.e., less than half of 1 per cent—was mined in Belgium, the remainder being imported mainly from France and Germany.

The 110 steel furnaces produced 2,466,630 tons of steel, of which 1,409,460 tons was finished steel; 110 puddling furnaces and 317 reheating furnaces produced 304,350 tons of finished iron and 448,400 tons of finished steel. There were in operation eighty hammers and 216 rolling mills for the production of the total of 2,162,210 tons of finished products, of which 1,161,425 tons was exported.

The total Belgian export of iron and steel during 1913 amounted to 1,762,170 tons, of which 213,203 tons was manufactured products. This represents an export of 81 per cent of the total produced. No

made possible by the efficient methods used at the plants and by the special quality of the products manufactured.

PRE-WAR PRODUCTION OF ZINC AND OTHER METALS

The Belgian zinc industry dates from the time Dony discovered the commercial production of zinc. His small shop in Liège, installed in 1808, was the cradle of the great zinc industry. In 1809 the zinc sold for 3.60 fr. per kg. (about 35c. per lb.). In 1810 Dony enlarged his shop and installed a plant of eight reverberatory furnaces with forty retorts, producing 200 kg. zinc per twenty-four hours. The price was then 2.60 fr. per kg. (about 25c. per lb.). The industry grew gradually until in 1913 there were 510 furnaces with 43,444 retorts and thirty-seven mills requiring 480,645 tons of ore, of which only 355 tons was mined in Belgium. The total production of zinc reached 204,225 tons, of which 87 per cent was exported.

In the zinc industry, as in the iron and steel industry, Belgium had to work hard to maintain its rank of a zinc-producing country (204,225 tons out of the total world production of 982,000 tons) with only 355 tons of zinc ores mined in the country and the other needed 480,290 tons imported from practically all the zinc-producing countries in the world.

Lead and silver are practically the only other metals produced in Belgium. In 1913 28,865 tons of lead ore, practically all imported, was treated for the production of 13,590 tons of lead; 132,220 tons of lead or silver byproducts and 48,890 tons of lead scrap were imported, from which 254,000 kg. of silver was recovered.

SITUATION OF THE BELGIAN INDUSTRY DURING THE WAR

The Belgian metallurgical industry during the war suffered from the systematic devastation of the plants by the Germans, from lack of raw materials and from the cutting off of the foreign markets on which practically all the Belgian industry has to rely. A series of sixteen photos shows clearly the extent of the devastation.

The two views on page 747 show as a typical example what took place as late as 1918. Thus on the left is shown a blast-furnace installation as it was in 1917 and on the right the same furnace installation as it was Nov. 20, 1918, after all the useful parts, including the Cowpers stoves and cranes, were shipped to Germany.

Some idea of the depressing status of the Belgian metallurgical industries during the war might be obtained by analyzing the following table, which summarizes the metallurgical production of Belgium from 1913 to 1918:

PRODUCTION IN TONS				
Year	Pig Iron	Steel	Zinc	Lead
1913	2,484,690	2,466,630	204,220	103,480
1914	1,454,490	1,396,300	145,925	70,980
1915	68,150	98,890	51,660	16,770
1916	127,825	99,371	22,930	15,560
1917	7,990	9,530	10,290	22,745
1918		10,540	9,245	20,630

The last Belgian blast furnace in operation was shut down in April, 1917. The production of steel in 1917 and 1918 was possibly due to the use of scrap iron as raw material and to two plants of the Province of Hainaut which for some reason enjoyed the particular good will of the Germans.

RECONSTRUCTION OF THE BELGIAN METALLURGICAL INDUSTRY

What this work implies may be surmised from the following table relating to the principal plants:

	Status Before the War, 1914	Status After the War In Working Condition
Coke ovens	2,554	993
Blast furnaces	59	4
Converters	49	8
Martin furnaces	26	19
Rolling mills	108	23

The smaller plants have undergone a similar fate.

The reconstruction work is making headway. Thus an official report stated that at the end of 1919 the iron and steel industries employed 60 per cent of the pre-war-time force, of which a great part was devoted to reconstruction work, and produced 34 per cent of the normal tonnage of iron products. During the same period the coke-oven plants employed 53 per cent of their pre-war force and produced 37 per cent of the normal coke tonnage.

The Belgians encounter many hardships in the struggle to revive their metallurgical industries. Among these hardships may be cited the depreciation of the money, labor conditions, lack of raw materials and what may be called *reverse dumping*. This consists in selling products at low prices in the country where produced and charging exorbitant export prices. Although these conditions handicap rapid recovery, the Belgians are working hard for the aim in view.

Synopsis of Recent Chemical & Metallurgical Literature

Composition of Coal Gas Obtained at Different Temperatures.—In studying the composition of coal gas obtained by the distillation of different coals at temperatures varying between 400 and 1,200 deg. C. and maintaining the temperatures at 600, 800, 1,000 and 1,200 deg. C. for some time and until only very small quantities of gas continue to distill at the considered temperature, LEO VIGNON (*Annales de Chimie*, May-June, 1920, pp. 288-292) has arrived at the following conclusions:

1. The unsaturated hydrocarbons C_2H_4 , C_2H_2 , C_3H_4 distill at below 600 deg. C.; at higher temperatures these hydrocarbons are broken up.

2. Methane and saturated hydrocarbons distill up to 800 deg. C. in very great quantities—namely, 60 to 84 per cent—but this percentage diminishes rapidly at a higher temperature.

3. The percentage of hydrogen in the distilled gas is from 2 to 25 up to 600 deg., is more abundant in the gas distilling between 800 and 1,000 deg., but decreases with gas obtained between 1,000 and 1,200 deg.

4. The percentage of carbon monoxide in the distilled gas varies between 3 and 11 (with an average of 6.5) according to the coal used, up to 850 deg. C. At temperatures above 1,000 deg. C. this percentage may reach 30 and even more.

5. By increasing the temperature of distillation the total volume of gas distilled increases, but the gas obtained at over 1,000 deg. C. has a low calorific value and contains in general great quantities of carbon monoxide.

Annealing Electrolytic Iron.—It is known that electrolytic iron contains quantities of hydrogen when leaving the electrolytic bath and that this gas forms hydrides, which are easily detected with the microscope, resulting in an increase of hardness. JEAN COURNOT

FIG. 1.

has worked out the necessary heat treatment for eliminating this hydrogen. He experimented upon test pieces, 6 cm. x 4 cm. in area, from a cathode sheet

FIGS. 2 AND 3. $\times 350$

6 mm. thick, varying the time and temperature of annealing.

Brinell hardness as a function of time and temperature of annealing is shown in Fig. 1, from which it can be seen that during the first ten minutes of annealing there is a rapid fall in hardness, this the more rapid the higher the temperature. The limiting hardness is about 83, which is reached only after many days at temperatures below 850 deg. C., two hours at 950 deg. C. or one hour at 1,050 deg. C.

Micrographic results are as follows: After one hour heating, the sample polished and etched for twenty seconds by a 4 per cent solution of nitric acid in alcohol shows generally a polyhedral structure. Fig. 2 shows the sample before annealing, and Fig. 3 the sample after one hour. (*Génie Civil*, Aug. 7, 1920, pp. 118-119.)

Recent Chemical & Metallurgical Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Ductile Nickel-Cobalt Alloy.—COLIN G. FINK has found that the non-ductility at ordinary temperatures of the alloys of nickel and cobalt is due to the presence of carbon in the alloy, and that such an alloy free from carbon, sulphur, phosphorus and basic impurities is ductile. An alloy containing twenty to thirty parts by weight cobalt and eighty to ninety parts nickel is produced in an electric furnace of the Coolidge type in an alundum crucible, special precautions being taken to prevent contamination with carbon, sulphur, etc., and when melted about two parts of manganese is added. The alloy may be rolled from 0.5 in. to 0.02 in. without intermediate annealing and is particularly suitable as a supporting and current lead wire for electric incandescent lamps, as it has but slight tendency to volatilize and spatter electrically. It has a low heat conductivity and therefore increases the efficiency of electric lamps, particularly in the case of miniature low voltage lamps. (1,342,993; assigned to General Electric Co., June 8, 1920.)

Cyanides From Ferrocyanides.—Ferrocyanide material—such as Bueh sludge obtained by treating coke-oven gas with ferrous sulphate—is added slowly to a boiling acid solution containing a small amount of finely divided copper. The acid used may be either H_2SO_4 or

HCl. If the former is used, a small amount of NH_4Cl or other chloride is added to accelerate the reaction. While the ferrocyanide is being introduced, an equivalent quantity of acid is added until the solution becomes concentrated with iron sulphate or chloride. The feed of ferrocyanide is continued as long as it is completely decomposed, thus practically neutralizing the free acid. At this stage copper cyanide is precipitated and this together with the residue of metallic copper is filtered off and returned to the still for the treatment of the next batch. The vapors from the still pass through condensers and fractionating columns which separate the water and discharge it outside of the apparatus so that the capacity of the still is increased and a more concentrated solution of ferrous sulphate and ammonium sulphate obtained. The HCN which passes on through the column is absorbed in alkali to form cyanides. (1,347,518; MAX E. MUELLER, of Youngstown, Ohio; July 27, 1920.)

Pyrophosphates.—HYLEMAN A. WEBSTER, of Columbia, Tenn., has been granted a patent on a process of producing pyrophosphates without fire. He precipitates magnesium pyrophosphate from an acid solution of mono-calcium phosphate (20 deg. Bé.) and magnesium acetate at 60 deg. C. according to the reaction:

The process used in the arts is according to the following reaction:

$NaH_2PO_4 + MgCl_2 + NH_3 \rightleftharpoons NH_4MgPO_4 + 2NaCl$ which upon heating to fusion temperatures $= Mg_2P_2O_7 + 2NH_3 + H_2O + 2NaCl$. As the acetic acid is worked in a cycle and would only suffer a percentage loss, it is apparent that the new process is the more economical. (1,346,148; July 13, 1920.)

Refractory Compound of Carbon and a Silicate Mixture.—A. J. HINCKLEY, of Niagara Falls, N. Y., produces a highly refractory article by combining fully shrunken and carefully graded carbon with high-grade fireclay. Hard coal is preferably used and should be as free as possible from laminations; this is calcined in an electric furnace to produce a fully shrunken product, which is graded by carefully screening out the over- and under-sized particles. The volume of the interstitial space is calculated and high-grade fireclay added in just sufficient quantity to fill the interstitial space. Water is then added to produce a plastic mass. After thorough pugging the heavy paste is ready for use. It is extruded under heavy pressure or may be tamped into place to form a furnace lining. After preliminary drying the article is burned at approximately 1,000 deg. C. The approximate volume ratio is 53 parts graded carbon particles to 47 parts finely ground fireclay; the carbon particles for a standard 9-in. brick are approximately 0.03 in. in diameter.

The product has a distinct electrical conductivity, the specific resistivity is of the order of 0.04 ohm. per c.c. It is mechanically strong and does not shrink or crack on exposure to very high furnace temperatures. At furnace temperatures higher than 1,000 deg. C. silicon carbide will be formed, this transformation producing an extremely refractory article. (1,346,959; July 20, 1920.)

Removal of Cobalt From Zinc Solution.—The usual treatment for the removal of impurities from the solution obtained by leaching zinc calcine with spent elec-

trolyte does not completely remove cobalt, the presence of which most adversely affects the subsequent electro-deposition of the zinc. DAVID AVERY and R. J. D. WILLIAMS have discovered that if the solution is treated with limestone for the precipitation of the iron and with finely divided zinc dust for the precipitation of any silver, arsenic, antimony, copper or cadmium that may be present (the usual method), the presence of arsenic more effectively secures the removal of cobalt. It is necessary to have a soluble arsenic compound present after the treatment with limerock; the treatment is more effective if the solution be heated to about 60 deg. C. and the addition of the zinc dust be made in stages. For complete removal of the cobalt a soluble compound of copper is also necessary and the presence of a small quantity of free sulphuric acid facilitates the precipitation. The agitation of the solution should be made without the access of air. (1,347,200, assigned to the Electrolytic Zinc Co. of Aust. Prop. Ltd.; July 20, 1920.)

Refining of Metal in Electric Furnace.—When refining steel in an electric furnace of the Heroult type it is necessary, in order to operate economically using the basic process, to charge the furnace with molten metal and refine with low voltage arc. This low voltage limits the length of the arc, and a current of relatively high amperage is initially required to properly refine the charge. Following this treatment the amperage is reduced and treatment continued with a reduced power input at practically the initial voltage. This method of operation is slow and uneconomical, unless the metal be added in the molten state, and to be able to refine a solid charge it has been necessary to use a longer arc at a higher voltage; this brings up the output but introduces difficulty from the overheating of the walls and roof of the furnace.

In order to overcome these and other difficulties R. H. BULLY, of Syracuse, N. Y., has developed a method of treatment which consists of initially applying a high-voltage relatively long arc to the charge and then reducing the length of the arc, at the same time keeping the kilowatt load practically constant. Suitable transformer and regulator equipment is described. (1,347,838; July 27, 1920.)

Electrolytic Concentrating Table.—H. II. GODFREY combines the action of a shaking concentrating table and that of electrolysis for the extraction of metals from ores. The bed of the table consists of a cathode and is made of a suitable material. At an adjustable distance above and parallel to the bed is a plate which constitutes the anode. The material to be treated is made into a pulp by the addition of a suitable electrolyte. (July 20, 1920; 1,347,026.)

Method of Producing Tungsten Alloys.—In the manufacture of tungsten steel considerable difficulty as well as a material loss of tungsten is experienced in adding the tungsten powder, the most suitable form of this metal, to the molten metal. Many methods have been tried to overcome these difficulties. J. H. DEPPELER has found that it is possible to compress the tungsten powder into dense coherent tablets and that these when added to a molten bath of the alloying metal sink to the bottom of the bath, the addition being accomplished without material loss of tungsten. (1,350,709, assigned to the Metal & Thermit Corp.; Aug. 24, 1920.)

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Cymene.—*p*-Cymene is prepared from residual terpenes, boiling at about 175 deg. C., from the manufacture of artificial camphor or pine-needle oil fractions boiling at about 175 deg. C., which consist essentially of *i*-limouene, by chlorination followed by steam distillation of the product. The *p*-cymene may be purified by treating with zinc chloride or other condensing agent or oxidizing-agents such as potassium permanganate. (Br. Pat. 142,738—1919. BRITISH & FOREIGN CHEMICAL PRODUCERS LTD., London, July 7, 1920.)

Organo-Metallic Compounds.—Aromatic arsenic acids are obtained by the reaction of aromatic diazo compounds upon acids, neutral, or alkaline aqueous or dilute alcoholic solutions of arsenious acid, in the presence of a copper salt and a reducing-agent appropriate to the medium used. Suitable reducing-agents are: for acid solutions, hypophosphorous acid or a mixture of sodium hypophosphite and hydrochloric acid, or cuprous hydrate; for neutral solutions, sodium hydrosulphite or sodium formaldehyde sulfoxylate; for alkaline solutions, sodium hydrosulphite, formaldehyde hydrosulphite, or formaldehyde sulfoxylate, or the sodium arsenate itself used in excess. The process may be carried out in cold or at a moderate temperature; when working in acid solution, the diazo compound may be replaced by the aromatic amine in conjunction with sodium nitrite. Examples are given of the preparation of phenylarsinic acid in acid, neutral, and alkaline solutions, using copper sulphate as the copper salt, sodium arsenite Na_2HAsO_3 or a solution of arsenious acid in caustic soda or sodium carbonate solution as the source of arsenic, and sodium hypophosphite, sodium hydrosulphite, or the excess of sodium arsenite as the reducing-agent in the acid, neutral, or alkaline solutions respectively. The following products are specified also: *p*-methylphenylarsinic acid, *p*-chlor-phenylarsinic acid, *p*-chlor-*m*-nitrophenylarsinic acid, *p*-bromophenylarsinic acid, *p*-brom-*m*-nitrophenylarsinic acid, *p*-methoxyphenylarsinic acid, *p*-methoxy-*m*-nitrophenylarsinic acid, *p*-ethoxyphenylarsinic acid, *p*-ethoxy-*m*-nitrophenylarsinic acid, phenylsulphonyl-*p*-aminophenylarsinic acid, *p*-oxyphenylarsinic acid, *p*-oxy-*m*-nitrophenylarsinic acid, and *p*-oxy-*m*-urethanophenylarsinic acid. Sodium arsenite of the formula Na_2HAsO_3 is obtained by fusing arsenious oxide with two molecular parts of sodium carbonate, in absence of air, dissolving the product in water, evaporating to a sirupy consistency, and allowing to stand for some time at 30-40 deg. C. (Br. Pat. 142,947—1919. A. MOUNEGRAT, Paris, France, July 14, 1920.)

Indophenols.—Indophenols are obtained by finely grinding and intimately mixing together equi-molecular parts of *p*-nitrosophenol and the free bases diphenylamine carbazole or other amines yielding indophenols, and introducing the mixture slowly with stirring into cold concentrated sulphuric acid. Liquid amines such as *o*-toluidine are similarly mixed to a paste with *p*-nitrosophenol, and the paste treated as described above. The indophenol from *p*-nitrosophenol and phenol is prepared similarly. The provisional specification also describes a process in which *p*-nitrosophenol is ground and mixed with the sulphate of a liquid amine as *o*-toluidine, and

further treated as above. (Br. Pat. 143,014—1919. BRASSARD & CRAWFORD, Wakefield, Yorkshire, and E. A. BUCKLE, Westminster, July 14, 1920.)

Treating Lead and Silver Ores.—The lead and silver in complex sulphide ores containing zinc such as Broken Hill ores, are treated by mixing the ore with hydrochloric in quantity sufficient for the desired reaction, and heating to a temperature above 100 deg. C. The ore is mixed with the acid, dried at a temperature below 100 deg. C., and heated at a higher temperature which may be 500 to 600 deg. C., preferably in a closed vessel. The operation is facilitated if some copper is present in the ore. The mixture of ore and acid may be allowed to stand some time before drying, and the furnace product may be moistened and left for some time before leaching. The product may be leached with hot brine containing some ferric chloride to dissolve both lead and silver chlorides with a minimum time of contact between liquor and ore. (Br. Pat. 142,854—1919. AMALGAMATED ZINC (DE BAVAY'S), LTD., Melbourne, Australia, July 14, 1920.)

Chloropicrin.—Consists in preparing this by the action of chlorine or picric acid or other suitable nitro-derivative of a phenol or of a naphthol in the presence of water and a basic material, such as metallic oxides, carbonates, or borates, preferably sodium or potassium hydroxide or carbonate. The basic material may be added in successive stages or wholly at the beginning. The temperature is preferably kept below normal atmospheric pressure. (Br. Pat. 142,878—1919. K. J. P. ORTON, University College, Bangor, Carnarvonshire, and W. J. POPE, University Cambridge, July 14, 1920.)

Arylarsenious Halides.—Monoarylarsenious halides are obtained from di- or tri-arylarsines by treatment with arsenious halides; and diarylarsenious halides are also obtained from triarylarsines by treatment with monoarylarsenious halides or with arsenious halides. Solvent and catalysts may be added. On a large scale, mono- and di-arylarsenious chlorides are obtained by vaporizing arsenious chloride and passing the vapor through or over the surface of the molten triarylarsine. In other cases, the reaction is performed by heating a mixture of the ingredients in an autoclave or under atmospheric pressure. (Br. Pat. 142,880—1919. W. J. POPE, The University, Cambridge, July 14, 1920.)

Treating Rubber Tree Bark.—Bark shavings from rubber trees are ground and masticated between rollers heated to about 275 deg. F., so as to knead the rubber with the bark and convert the whole into a dough-like or plastic mass. The product, after being mixed with a vulcanizing-agent and vulcanized, is suitable for the manufacture of tapping-cups, coagulating-dishes, floor matting, etc. Alternatively, the vulcanizing agent may be added prior to grinding, and the raw material may be treated in a scrap-washer and creping machine in the known manner for the extraction of raw rubber. (Br. Pat. 142,926—1919. R. T. SMITH, London, July 14, 1920.)

Recovering Material From Linoleum Scrap.—In a process for working up linoleum scrap into new linoleum by treating with organic solvents, only sufficient solvent is used to soften the scrap and enable the jute fibers to be separated by mechanical means from the softened mass of binding cement, ground cork, coloring matter, etc. For example, 1,000 kg. of broken up lino-

leum scrap is treated with 500 kg. of alcohol in an autoclave for about two hours at a temperature of 80 to 140 deg. C., resulting in the reduction of the scrap to a soft crumbly pulp. The alcohol is then distilled off, and the pulp is fed on to vibrating sieves to separate the jute fibers from the linoleum pulp. The regenerated substance is finally heated to a temperature of 100 to 120 deg. C. to restore the qualities of toughness and glutinousness of the binding cement, which had been depolymerized during the treatment with the solvent. (Br. Pat. 143,561—1919. V. SCHOLZ, Jauer, and C. TIEDEMANN, Coswig, both in Germany, July 28, 1920.)

Treating Slag.—Molten slag is converted into foam by blowing steam or other gas through it, and this foam is rapidly cooled to a temperature at which the slag is still plastic, but the porosity becomes stable, the resulting material being molded into bricks or the like and allowed to solidify. In an example, a slag

having the composition 50 per cent silica, 15 per cent alumina, 30 per cent lime and 5 per cent magnesia is introduced into a vessel 1 provided with a stirrer 2, at a temperature of about 1,400 deg. C. Water or water and steam or other gas is introduced through an opening 4, and, on stirring, a foam is produced at a temperature of about 1,000 deg. C, which flows through a conduit 5 on to water-cooled rollers 6, whence it emerges as a ribbon at about 800 deg. C., which falls into cast-iron molds on a conveyer 7 which moves in the direction of the arrow. Rollers 8 level the surface and remove any excess of foam. The foam may be further cooled by an air or like blast between the rollers 6 and the molds. If objectionable gases are produced during the conversion into foam, the operation should be carried out in an oxidizing atmosphere. (Br. Pat. 143,500—1919. NORSKE AKTIESELSKAB FOR ELEKTROKEMISK INDUSTRI, Christiania, July 21, 1920.)

Waterproofing Paper.—Paper is waterproofed and rendered impervious to air so that it may be used as a substitute for rubber or leather for making diaphragms for gas meters and gas lighters, or for the manufacture of purses, etc., by impregnation with a warm solution of animal and vegetable glutinous substances, followed, after drying, by rubbing in fat, whale oil, etc. Long-fibered paper, such as japan paper, is preferably employed. A suitable impregnating solution consists of gelatine 2 parts, agar-agar or arrowroot 1 part, potassium bichromate 0.5 part, calcium chloride or glycerine 3 parts, and ammonium carbonate for reducing flammability 3 parts, all dissolved in 100 parts of water. Gelatine alone may be used when brittleness is not objectionable, and the after treatment with fat or oil is necessary only when the material in use is alternately wetted and dried. (Br. Pat. 143,235—1919. L. HEILBRONNER, Stuttgart, July 21, 1920.)

Anthraquinone.—Crude anthraquinone is purified by heating it dissolved in an inert solvent with alkaline substances (aqueous solutions of caustic alkalis, alkali carbonates, calcium hydroxide, etc.) or sulphuric acid; chlorobenzene or coal-tar naphtha are specified as suitable solvents. (Br. Pat. 143,885—1919. KINZLBERGER & Co., Prague, Czechoslovakia, July 28, 1920.)

Acetaldehyde.—In the manufacture of acetaldehyde by passing acetylene into acid solutions containing mercury salts, the catalyst is continuously regenerated in the reaction liquid by electrolytic oxidation, the arrangement being such that excess of metallic mercury is always present at the anode. The reaction liquid may contain large quantities (over 10 per cent) of mercury salt, the rapid reduction of such concentrated solutions to mercury being offset by the anodic oxidation of the reduced mercury. Examples are given in which (1) the liquid contains at the commencement both dissolved mercury salt and a mercury anode; (2) the liquid at the start contains only mercury salt, the reduced mercury collecting and being oxidized at a platinum anode; (3) the liquid at the start contains only a mercury anode, the current of acetylene not being passed until sufficient mercury salt has been formed by the electrolysis. Sulphuric acid is employed as reaction liquid in the above-mentioned examples, but other inorganic or organic acids may be used. The cathode may be of mercury, lead, platinum, etc., and may be enclosed in a diaphragm chamber or not. (Br. Pat. 143,891—1919. CHEMISCHE FABRIK GRIESHEIM-ELEKTRON, Frankfurt-on-Main, July 28, 1920.)

Artificial Filaments and Fabrics.—An artificial textile fabric is made from filaments prepared from solutions of, for example, viscose, cuprammonia cellulose, collodion, gelatine or cellulose acetate, and in which are incorporated bubbles of air or inert gas; fabrics manufactured of such hollow filaments are very light, opaque and soft to the touch. The introduction of air, etc., bubbles is effected by forming an emulsion of the selected solution and air—for example, by directly blowing in air, or by means of injectors, or by heating devices—and the emulsion can be made more permanent by the addition of soap, albumen, gelatine, etc. The process is applicable to the manufacture of continuous filaments such as threads for spinning, or films, plates or bands, and also of non-continuous filaments such as tops and noils. (Br. Pat. 143,253—1919. L. DRUT, Villeurbanne, France, July 21, 1920.)

Fibrous Compositions.—Vegetable fibers are mixed with casein in the form of paste and the mixture is molded under pressure and heat. In an example, fibers are immersed in a bath containing one kilo of casein paste consisting of 88 per cent casein and 12 per cent ammonia to 15 liters of water. The fibers are drained, placed in molds, compressed, and heated to about 130 deg. C. to drive off the water and ammonia. Lime, carbonate of magnesia, borate of soda, etc., may replace the ammonia. Articles may be ornamented by coating them with sawdust before molding. (Br. Pat. 143,258, 1919. E. E. MOUGEON, Montoux, France, July 21, 1920.)

Dialkyl Sulphates.—Dialkyl sulphates are prepared by the reaction of sulphur trioxide as such or in the form of fuming acid, upon the alcohols in the presence of dehydrating-agents—e.g., phosphorus pentoxide or anhydrous sodium or copper sulphate; diluents such as

carbon tetrachloride may be added; the product of the reaction is worked up by distillation *in vacuo*, extraction by solvents, etc. Examples are given of the preparation of diethyl sulphate. (Br. Pat. 143,260—1919. L. LILIENFELD, Vienna, July 21, 1920.)

Purifying Fats, etc.—Edible oils, fats and the like are purified by converting any fatty acids present into glycerides *in situ*. In an example, 1 lb. of palm or coconut oil and 2 lb. of glycerine, with a contact substance, such as kieselguhr or titanium dioxide deposited on kieselguhr, are sprayed or agitated together in a vessel maintained at about 140 deg. C. and under a vacuum of about 28 in. for, say, fifteen hours. The product is allowed to settle and the oil decanted, washed with water and filtered. Hydrogenation, deodorization and purification as described in Specification 135,295 may proceed at the same time or after esterification. (Br. Pat. 143,321—1919. G. CALVERT, Twickenham Park, Middlesex, July 21, 1920.)

Dyeing With Mordant Dyes.—Meta-tungstic acid or compounds or salt thereof—e.g., phosphotungstic acid, silicotungstic acid or antimony-tungstic acid—are employed in dyeing textile fibers, paper, wood, leather, gelatine, etc., with acid dyes containing amino and sulphonic groups; either the tungstic acid compound is added to the dye-bath or the dyeing is after-treated therewith. The tungstic acid compounds are also used in making lakes from the dyes in question. Examples are given of the dyeing of wool, paper pulp, and leather, and of the manufacture of barium-aluminum lakes, phosphometatungstic acid being used in each case. (Br. Pat. 143,242—1919. FARBENFABRIKEN VORM. F. BAYER & Co., Leverkusen, near Cologne, July 21, 1920.)

Gray Iron.—In the production of gray iron in two stages, a white iron is first obtained by smelting at a temperature of 1,200 to 1,300 deg. C. and the product is refined in an electric or other furnace at a temperature of 1,500 deg. C. with additions of carbon and silicon. The white iron, if smelted in an electric furnace, contains carbon 2 per cent, silica 0.5 per cent and sulphur 0.3 per cent; when a blast furnace is used the iron contains 3 per cent of carbon. The refined product contains 3 per cent of carbon and 1.5 per cent of silicon. (Br. Pat. 143,596—1919. G. J. STOCK, Bradford, Yorkshire, July 28, 1920.)

Purifying Coal Gas.—Carbon disulphide, thiophene and similar impurities in coal gas are dissociated to form sulphuretted hydrogen by passing the heated gas over heated alumina, bauxite or ignited magnesite. The sulphuretted hydrogen is then removed from the gas by the usual methods. When the efficiency of the material has become impaired, owing to the deposition of carbon, it may be revived by the passage of air over the heated mass. (Br. Pat. 143,641—1919. F. W. BERK & Co. and J. J. HOOD, both of London, July 28, 1920.)

Cementation.—A mixture used in the cementation of iron and steel at a temperature of 700 to 800 deg. C. contains potassium ferro and ferri cyanides, potassium chromate or bichromate, and charcoal. Large articles are preferably preheated before insertion into the mixture. The metal may afterward be hardened in a bath containing seasalt together with ammonium chloride or caustic soda, or both. (Br. Pat. 143,746—1919. M. L. M. LUTTENSCHLAGER, Mulhouse, July 28, 1920.)

Current Events

in the Chemical and Metallurgical Industries

Sub-Committee on Standardization of Petroleum Specifications to Convene

The Technical Sub-Committee of the Committee on Standardization of Petroleum Specifications, appointed some time ago by President Wilson, will hold a meeting at the offices of the Bureau of Mines, Washington, D. C., on Monday, Oct. 18, at 10 a.m., to give further consideration to Government specifications on gasoline, kerosene, fuel and lubricating oils. The meeting is to be open to all persons interested, and it is the desire of the committee that as many representatives of the oil refining and automotive industries as possible be present.

Dr. G. W. Gray, of New York, chairman of the committee, particularly requests that any refineries who feel that the present specifications may be unjust send their technical men to this meeting, as the committee intends to take up all the specifications for petroleum products that have been issued up to the present time with a view to possible revisions. This includes the specifications for Government purchase of gasoline, kerosene, fuel and lubricating oils.

The committee also plans to consider new specifications for lubricants and other products.

Coal-Tar Trust Formed in Germany

Official advices reaching Washington tell of the formation in Germany, under legal authority, of an economic union to regulate the coal-tar trade. The organization is composed of practically all concerns engaging in the coal-tar industry. The organization is to supervise import and export matters, but is precluded from reducing importations for the purpose of maintaining high levels or prices in Germany. A committee has been appointed to fix prices at which coal tar, tar oil and briquet tar are to be sold. Another committee is to decide what amount of crude tar is to be assigned to the various plants.

Only such plants will be recognized as legal refineries as conform to certain technical standards and agree to abide by prevailing prices.

The formation of this union is regarded as very significant by some officials in Washington since they see in it a continuation of Germany's pre-war methods of meeting competition abroad.

Plenty of Cars for Fertilizers

Through an arrangement made between the National Fertilizer Association and transportation authorities the movement of fertilizers during the season just closed was highly satisfactory despite the transportation shortage. Under the agreement box cars were to be furnished for 75 per cent of each plant's daily requirements. To offset the smaller number of cars furnished the shipping season was begun one month earlier. By extending the season the entire tonnage was moved to the complete satisfaction of the National Fertilizer Association.

Working for Soil Improvement

The work of the Soil Improvement Committee of the National Fertilizer Association is to be expanded materially. The main office of the committee has been moved from Chicago to Washington. A branch office will be continued in Chicago, but the Baltimore office of the committee has been closed. W. D. Hurd is the director of the committee. The main function of Dr. Hurd's organization is to encourage the proper use of fertilizer and to conduct an educational campaign among the farmers of the country looking to the more general recognition of the importance of fertilizers in economical farm management.

Dr. Hurd is of the opinion that fertilizers are going to be called upon to play an increasingly important part in agriculture, due to the increase in labor and other costs. Each year more farmers become aware that there are few soils which possess all the constituents for the maximum plant growth. During the transportation shortage and other conditions arising out of the war fertilizers have not been used to the extent necessary. As a result the demand for fertilizer is expected to increase very materially as soon as conditions are nearer normal.

One of the matters now receiving particular attention by the Soil Improvement Committee is the effort to bring home to the farmer the advantage of purchasing high-analysis fertilizers in preference to those of low analysis. There is an additional reason for urging such purchases since the increase in freight rates because the more concentrated product is relatively cheaper to transport.

Industrial Information Bureau in China

Of interest to those who do, or desire to do, business in China is the announcement that beginning with February, 1921, the Government Institute of Technology at Shanghai, China, will open a Bureau of Information for Alumni. The school is under Chinese Government support and prepares engineers and railway administration men with a technical education equivalent to that of an engineering school. These men often are located away from the port cities, and when they desire information regarding equipment they find it difficult to obtain it. To meet this need the school is about to open this bureau. Manufacturers who are interested are invited to send catalogs, specifications, designing data, approximate costs, samples or models. In case samples are sent an attempt will be made to place them in running order. No sales will be made or attempted. Impartial information alone will be offered.

A member of the faculty is now in America on leave and he will be glad to communicate further with any who desire information regarding the Chinese field. Address H. A. Vanierbeck, 5 Canmann Pl., Somerville, N. J., until Dec. 1, 1920, and Box 951 U. S. P. O., Shanghai, China, after that date.

Exports of Dyes and Dyestuffs From the United States

Dyes and dyestuffs exported from the United States to the various countries during August amounted to \$2,111,095, of which \$1,151,196 worth was aniline dyes and \$336,718-worth was logwood extract. China was by far the largest importer of these goods, the trade being valued at \$547,311. Exports to England amounted to \$318,332. The value of the exports of dyes and dyestuffs to the various countries from the United States during August, 1920, is shown in the following table:

Countries	Aniline Dyes	Logwood Extract	All Others
Belgium	\$73,765	\$4,557	\$9,000
Denmark	1,749	1,553	664
Finland	2,060		
France		57,581	19,756
Greece	7,848		4,688
Italy	46,989	88,969	9,697
Netherlands	416	8,069	940
Norway	1,644		
Portugal	9,746	3,000	10,424
Spain	4,748	4,670	19,329
Sweden	27,857		290
Switzerland	2,860	3,462	3,500
Turkey in Europe	3,500

Chemical Manufacturers Participating in Crop Protection Institute

Eleven manufacturers of insecticides and fungicides have already indicated their desire to become company members of the Crop Protection Institute, organization of which was completed under the auspices of the National Research Council on Sept. 28. This organization has planned to foster research and co-operation in plant life protection, use of insecticides and fungicides, and similar or related activities. The officers who are serving at present are: Chairman, W. C. O'Kane, New Hampshire State Entomologist; secretary, H. E. Howe, National Research Council; treasurer, G. R. Cushman, General Chemical Co. The board of trustees will be made up of thirteen persons appointed as follows: Three by the American Association of Economic Entomologists, three by the American Phytopathological Society, two by the Association of Official Agricultural Chemists, one by the National Research Council, three by manufacturers of insecticides and fungicides and one by the manufacturers of equipment and supplies used in this industrial work.

Additions to Carnegie Tech Faculty

The faculties of the division of science and engineering and of the division of industries of the Carnegie Institute of Technology have been strengthened this year by a large number of new appointees. In the division of science and engineering are C. R. Clutter, Lauren C. Hand and Frank E. Rupert, instructors in chemical engineering; R. W. Boreman, W. H. Michner and A. Press, instructors in physics; Charles A. Blodgett and Fred J. Evans, instructors in civil engineering; W. S. McKee, instructor in machine design; David C. Saylor, instructor in mechanical engineering; W. A. Copeland, instructor in metallurgical and mining engineering; W. Z. Price, assistant professor in mining engineering, and C. G. Simpson, instructor in the mechanics department. In the division of industries are Charles B. Walker and F. N. Talley, instructors in chemistry, and James Creech, instructor in presswork, in the printing department.

May Load Less Phosphate Rock

Loading and unloading requirements applying to phosphate rock have been reduced on Shipping Board vessels. This concession is the result of conferences, extending over several months, between officials of the Shipping Board and of the National Fertilizer Association.

Prior to the new arrangement it was necessary to load and discharge vessels at the rate of 1,200 tons daily. In the future the requirement will be 1,000 tons daily in loading vessels and 800 tons daily in removing the cargo.

The new regulation affects the large tonnage of phosphate rock which moves in coastwise traffic from Tampa, Port Tampa and Boca Grande, Fla., to Savannah, Charleston, Wilmington, Norfolk, Baltimore, Philadelphia, Carteret, N. J., and Boston.

Personal

E. B. BALL, Assistant Secretary of Agriculture, spoke before the Chicago Chamber of Commerce recently on the world food supply's dependence on science.

Dr. G. HOWARD CARTLEDGE has recently been appointed associate professor of chemistry in Johns Hopkins University.

CLINTON V. CONLEY, who received his master's degree at the University of Chicago this month, is now research chemist for Procter & Gamble Co., Cincinnati, Ohio.

HERBERT HOOVER has been appointed a member of the advisory board for the Eastern Industrial Region Superpower Survey, now being conducted by the Geological Survey. Mr. Hoover will serve as consulting mining engineer on the board, which is assisting the Government in the development of plans for a vast superpower system stretching from Boston to Washington and designed to supply electrical power to railroads, public utilities and private industry throughout that territory.

Dr. OLIVER KAMM has resigned his position as assistant professor in organic chemistry in the University of Illinois in order to accept one as director of research for Parke, Davis & Co., of Detroit, Mich. Dr. Kamm was formerly chief of the research section of the department of technical control of the American Writing Paper Co., Holyoke, Mass., and still retains his connection with that company as a member of its consulting staff.

Dr. A. B. MACCALLUM, formerly administrative chairman of the Honorary Advisory Council for Scientific Research of Canada, has been appointed professor of biochemistry at McGill University, Montreal, Canada.

R. J. QUINN has recently been appointed Chicago district sales manager of the Mathieson Alkali Works, with an office at Room 617, Webster Bldg., 327 South La Salle St. The plants of this company are located at Niagara Falls and at Saltville, W. Va.

HENRY N. THOMSON, at one time head chemist for the Anaconda Co. and later superintendent of International Smelter, Tooele, Utah, has been appointed to the chair of metallurgy, University of British Columbia, Vancouver.

The following have become members of the staff of the department of chemistry of the College of the City of New York: Wylie McGee Billing, Harry P. Coats, Alexander Cohen, Alexander C. Glennie, Nathan Hecht and Foster D. Snell.

Additional appointments of research associates at the Bureau of Standards have been made as follows: E. N. Turnquist and G. G. Sward, appointed by Sears, Roebuck & Co., to study methods of standardization of mechanical devices and physical properties of products and standardization of commercial articles from a chemical basis. H. M. Westergaard, by the American Concrete Association, to work on investigation of flat-slab concrete and tile structures. C. J. Whittlesey, by the Gypsum Industries Association, to work upon the properties of gypsum products. J. P. Cockey, by the Super Cement Co., Ltd. (America), to participate in oil investigations in connection with cement.

Current Market Reports

The Iron and Steel Market

Pittsburgh, October 8, 1920.

The iron and steel market, generally speaking, is losing strength at the moment more rapidly than was expected. That a general readjustment had begun was recognized some time ago, but of late it has been thought that the momentum of the industry would carry it through the year or perhaps through the winter, with respect to tonnage output. By a close analysis it may be taken that the real turning point occurred as early as June 1, buying since then having been on a conservative scale, except that on account of the Steel Corporation quoting much lower prices than the independents its business kept up, no decrease in unfilled obligations being shown until the month of August. In the case of pig iron there were advances in nearly all districts in August, but the buying movement was extremely small, and the price advances could almost be said to be simply "on paper." The advanced prices were at any rate paid in few cases except for very early deliveries, so that in essence they represented a delivery premium.

Even should the production of steel decline sharply in the next few weeks, the industry would really have run on its momentum for some time. The market had been supported, moreover, by the scarcity of deliveries produced by rail transportation conditions, which became poor before consumers had been able to stock up after the scarcity produced by the steel strike inaugurated only a trifle more than a twelvemonth ago.

PRODUCTION

The beginning of curtailment in steel production seems to have begun, but the cases are few, involving only some mills that had been seeking the highest possible prices, and thus had leaner order books than the average mill. Production of steel at the present time is at the highest rate since before the rail strikes began April 1, there having been a continuous increase since July. The probability is that October as a whole will show the heaviest production since March, and the output may even make a new record

entirely, as the operations of the larger mills easily over-balance such curtailment as is in prospect for some of the smaller mills. The March production rate in ingots was about 45,200,000 tons per annum.

PIG IRON DECLINING

In the past pig iron prices have always been more sensitive to adverse influences than steel prices, perhaps because pig iron contracts are customarily carried out, while many steel contracts are in the nature of options, and if a mill reduces its open prices it is likely to be called upon to adjust contracts it is carrying on its books. At the present time, therefore, particular attention is being given in trade circles to the pig iron market. Actual values are recognized as being distinctly lower than the prices attained in the advance last August, but a difficulty is that inquiry is so light that actual market prices are but slowly developed, and in most cases there is simply a nominal market price, the real value not having been indicated by actual transactions. At the end of August the valley market was quotable, after the advances, at \$48.50 furnace for bessemer and basic and at \$50 for foundry and malleable. On a small transaction, as noted in last report, the valley foundry iron market became quotable at \$47. Now there are negotiations on basic iron, one or two buyers expecting to do about \$40, and quotations are understood already to have been made at \$44 or \$45. There is a report of one sale at \$46. In the course of a few days enough business will probably have been done to show where the market stands for the time being.

NO INQUIRY IN BESSEMER

In bessemer there has been no inquiry and the market has to be quoted at \$48.50 in lieu of any distinct information to the contrary, although no one doubts that on an inquiry for a few thousand tons one could secure a considerably lower price. The one thing that seems clear at the moment is that those who predicted, during recent advances, that pig iron would eventually decline as rapidly as it was then advancing were conservative. Indications now are that it will decline more rapidly.

STEEL PRICES

On account of the large amount of business independent steel makers as a whole have on books there is resistance to price declines, but the resistance is not adequate in all cases. In the case of plates 3.25c., which it was thought would prove a sticking point for the market as the delivery premiums disappeared, is now not a minimum but a price "to shoot at," to use an expression common in the trade, the mill usually feeling that the price must be shaded in order to secure an order. A very unattractive specification has been placed at 3.15c., while a fairly desirable order can be placed at 3.10c. and on a lot of several thousand tons of car plates the flat price of 3c. has been made. The Steel Corporation, which has adhered to the Industrial Board price of 2.65c., is receiving the bulk of such business as comes out. In structural shapes the 3.10c. price which was recognized as the minimum of the independents has been shaded to 3c. Bars, however, seem quite firm at 3c.@3.25c. Sheets are softening a trifle, but mills are so well sold up that there is little competition.

The Chemical and Allied Industrial Markets

New York, October 8, 1920.

Conditions remaining about the same, there is very little to be noted in any of the markets. Buying interests are still inactive, and as a matter of fact they have had no reason to change their attitude, as the list in general has been well sustained.

The following table will give an idea of a few items that during the past year have remained fairly steady:

	Today	Last Week	Last Month	Last Year
Ammonium sulphate	\$0 07½ @ \$0 08	\$0 07½ @ \$0 08	\$0 06½ @ \$0 07	\$0 05½ @ \$0 06
Calcium peroxide	1 50½ @ 1 70	1 50½ @ 1 70	1 50½ @ 1 70	1 50½ @ 1 70
Potassium bichromate	.34½ @ 36	.34½ @ 36	.36½ @ 40	.28½ @ 30
Potassium chlorate	.18½ @ 20	.18½ @ 20	.17½ @ 20	.19½ @ 20
Sodium borate	.09½ @ 11	.09½ @ 11	.09½ @ 11	.07½ @ .08½
Sodium hyposulphite	.03½ @ .04	.03½ @ .04	.03½ @ .04	.02½ @ .03½

NAVAL STORES

Far from advancing the *rosin* market has rather continued on the decline, which has been brought about by the extremely dull condition existing in the South. *Turpentine* is not an exception and the recession can be traced daily by a 1@2c. drop below the previous day's closing price. Current quotations are \$1.30 per gal., which, compared with the price a week ago, represents a 9c. drop. The following table shows the course of *turpentine* and the *rosins* for the past year:

	Today	Last Week	Last Month	Last Year
Turpentine	\$1.30	\$1.39	\$1.55	\$1.70
Rosin:				
B-I	12.90	13.00	14.00	18.25
E-I	12.90	13.00	16.00	18.50
W-I-WW	13.00	13.00	17.25	23.50

The Baltimore Market

Baltimore, Md., October 6, 1920.

The local market on fertilizer materials continues in a demoralized condition, with a general downward trend of prices. A number of manufacturers report that orders for fall shipment have not come up to their expectations; as a consequence it will be necessary for them to carry over rather heavy stocks of materials until spring. The car situation is reported as greatly improved and we hear few complaints as to shortage of cars. As mentioned above, prices of materials are generally working lower and for that reason the buyers are showing hesitation in purchasing, thinking that the bottom has not yet been reached.

ACID PHOSPHATE

It is generally believed that the manufacturers have covered fairly well on their requirements for spring, also that the producers of this commodity are well sold up. An occasional export order is noted and spot parcels are changing hands around \$18 per ton, basis 16 per cent bulk, run of pile.

NITRATE OF SODA

Importers are quoting this commodity at \$3.30@3.40, ex-vessel Atlantic ports for arrival prior to Jan. 1. For arrival after the turn of the year, asking prices are 10@20c. higher. Spot lots of nitrate, however, are being offered around \$3.15 and a sale was reported recently on this market at that price. It is said that at the present rate of exchange it is costing about \$3.70 to deliver nitrate to Atlantic ports at this time, which would indicate that sales at prices mentioned involve rather heavy losses for nitrate merchants.

SULPHATE OF AMMONIA

Resales of sulphate of ammonia, basis 25 per cent bulk, have been noted on this market at \$4.75. This shows a drop of 75c. per cwt. from the nominal quotation given in last report.

POTASH

The various grades of potash salts are also showing a downward trend on price. Kainit and manure salts were reported being offered recently as low as \$1.60 per unit of K.O. Nominal quotations on this market are slightly higher than this figure. Muriate of potash is quoted nominal at \$2.20 per unit. Nebraska potash is held under contract for forward delivery at the price of \$2 per unit f.o.b. mines. There is no report of any sales for delivery forward from Nov. 1.

FISH SCRAP

The price of menhaden fish scrap worked as low as \$6 per unit, delivered Baltimore, but has since shown some recovery, as a sale was reported this week at \$6.25 and 10c. delivered Baltimore. The fishing in Chesapeake Bay has been exceptionally good for the last few weeks and as a consequence good tonnages of scrap are being made. It is also reported that the fish are yielding considerably more oil than they did through the summer months.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

	Carlots	Less Carlots

Sulphur dioxide, liquid, cylinders.....	100 lb. 3.80 - 4.35	
Sulphur (sublimed), flour.....	100 lb. 3.40 - 3.90	
Sulphur, roll (brimstone).....	lb. 42 1/2 - 44	
Tin bichloride (stannous).....	lb. 45 - 46	
Tin oxide.....	lb. 16 - 18	
Zinc carbonate, precipitate.....	lb. 13 - 13 1/2	
Zinc chloride, gran.....	lb. 45 - 49	
Zinc cyanide.....	lb. 12 - 13	
Zinc dust.....	lb. 17 - 25	
Zinc oxide, U. S. P.....	lb. 03 1/2 - 03 1/2	
Zinc sulphate.....	lb. 04 - 06	

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude.....	lb. \$1.30 - \$1.40
Alpha-naphthol, refined.....	lb. 1.50 - 1.65
Alpha-naphthylamine.....	lb. 48 - 52
Aniline oil, drums extra.....	lb. 34 - 36
Aniline salts.....	lb. 90 - 1.00
Anthracene, 80% in drums (100 lb.).....	lb. 2.00 - 2.10
Benzaldehyde (f. f. e.).....	lb. 1.35 - 1.40
Benzidine, base.....	lb. 1.15 - 1.25
Benzidine sulphate.....	lb. 85 - 90
Benzoic acid, U. S. P.....	lb. 35 - 40
Benzoin of soda, U. S. P.....	gal. 33 - 38
Benzene, pure, water-white, in drums (100 gal).....	gal. 15 - 40
Benzene, 90% in drums (100 gal).....	gal. 25 - 35
Benzyl chloride, 95-97%, refined.....	lb. 3.50 - 4.00
Benzyl chloride, tech.....	lb. 70 - 75
Beta-naphthol benzoate (nominal).....	lb. 65 - 70
Beta-naphthol, sublimed (nominal).....	lb. 2.25 - 2.40
Beta-naphthol, tech (nominal).....	lb. 18 - 19
Beta-naphthylamine, sublimed.....	lb. 23 - 25
Cresol, U. S. P., in drums (100 lb.).....	gal. 1.10 - 1.15
Ortho-cresol, in drums (100 lb.).....	gal. 1.05 - 1.10
Cresylic acid, 97-99%, straw color, in drums.....	gal. 65 - 75
Cresylic acid, 95-97%, dark, in drums.....	gal. 65 - 75
Cresylic acid, 50%, first quality, drums.....	lb. 07 - 10
Dichlorobenzene.....	lb. 1.50 - 1.60
Dichloraniline.....	lb. 90 - 1.00
Dimethylaniline.....	lb. 30 - 37
Dinitrobenzene.....	lb. 32 - 35
Dinitrochlorobenzene.....	lb. 45 - 55
Dinitronaphthalene.....	lb. 40 - 45
Dinitrophenol.....	lb. 38 - 40
Dinitrotoluene.....	lb. 80 - 85
Dip oil, 25%, tar acids, car lots, in drums.....	gal. 1.90 - 2.05
Diphenylamine (nominal).....	lb. 1.25 - 1.30
H-acid (nominal).....	lb. 18 - 20
Meta-phenylenediamine.....	lb. 2.00 - 2.40
Monochlorobenzene.....	lb. 12 - 14
Monochloraniline.....	lb. 16 - 17
Naphthalene crushed, in bbls. (250 lb.).....	lb. 16 - 17
Naphthalene, flake.....	lb. 16 - 17
Naphthalene, balls.....	lb. 75 - 85
Naphthionic acid, crude.....	lb. 14 - 19
Nitrobenzene.....	lb. 40 - 50
Nitronaphthalene.....	lb. 18 - 25
Nitrotoluene.....	lb. 3.25 - 4.25
Ortho-amidophenol.....	lb. 15 - 20
Ortho-dichlorobenzene.....	lb. 80 - 85
Ortho-nitrophenol.....	lb. 25 - 30
Ortho-nitrotoluene.....	lb. 35 - 40
Ortho-toluidine.....	lb. 2.50 - 3.00
Para-amidophenol, base.....	lb. 2.50 - 3.00
Para-amidophenol, HCl.....	lb. 08 - 12
Para-dichlorobenzene.....	lb. 1.10 - 1.15
Paranitraniline.....	lb. 1.10 - 1.15

Para-nitrotoluene.....	lb. 1.25 - 1.40
Para-phenylenediamine.....	lb. 2.50 - 2.65
Para-toluidine.....	lb. 2.00 - 2.25
Phthalic anhydride.....	lb. 60 - 70
Phenol, U. S. P., drums (dest.), (240 lb.).....	lb. 12 - 20
Pyridine.....	gal. 2.00 - 3.50
Resorcinol, technical.....	lb. 4.25 - 4.50
Resorcinol, pure.....	lb. 6.25 - 6.75
Salicylic acid, tech., in bbls. (110 lb.).....	lb. 45 - 50
Salicylic acid, U. S. P.....	lb. 45 - 50
Salol.....	lb. 90 - 1.00
Solvent naphtha, water-white, in drums, 100 gal.....	gal. 30 - 35
Solvent naphtha, crude, heavy, in drums, 100 gal.....	gal. 20 - 26
Sulphanilic acid, crude.....	lb. 32 - 35
Toluidine.....	lb. 1.70 - 2.50
Toluidine, mixed.....	lb. 45 - 55
Toluene, in tank cars.....	gal. 35 - 40
Toluene, in drums.....	gal. 38 - 40
Xylidines, drums, 100 gal.....	lb. 50 - 65
Xylene, pure, in drums.....	gal. 47 - 50
Xylene, pure, in tank cars.....	gal. 45 - 50
Xylene, commercial, in drums, 100 gal.....	gal. 32 - 35
Xylene, commercial, in tank cars.....	gal. 30 - 35

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark.....	lb. \$0.33 - \$0.38
Beeswax, refined, light.....	lb. .34 - .37
Beeswax, white pure.....	lb. .60 - .65
Carnauba, No. 1 (nominal).....	lb. .90 - .95
Carnauba, No. 2, regular (nominal).....	lb. .85 - .86
Carnauba, No. 3, North Country.....	lb. .35 - .36
Japan.....	lb. .18 - .20
Montan, crude.....	lb. .14 - .15
Paraffine waxes, crude match wax (white) 105-110 m.p.....	lb. .09 - .09 1/2
Paraffine waxes, crude, scale 124-126 m.p.....	lb. .09 1/2 - .11
Paraffine waxes, refined, 118-120 m.p.....	lb. .11 - .11 1/2
Paraffine waxes, refined, 125 m.p.....	lb. .12 - .13
Paraffine waxes, refined, 128-130 m.p.....	lb. .13 - .15
Paraffine waxes, refined, 134-135 m.p.....	lb. .16 - .17
Paraffine waxes, refined, 135-137 m.p.....	lb. .17 - .18 1/2
Stearic acid, single pressed.....	lb. .20 - .21
Stearic acid, double pressed.....	lb. .22 - .23
Stearic acid, triple pressed.....	lb. .24 - .25

NOTE—Paraffine waxes very scarce.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940.....	gal. \$2.15
Pine oil, pure, dist. dist.....	gal. 1.80
Pine tar oil, ref., sp. gr. 1.025-1.035.....	gal. .48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.....	gal. .35
Pine tar oil, double ref., sp. gr. 0.965-0.990.....	gal. .85
Pine tar, ref., thin, sp. gr. 1.080-1.960.....	gal. .36
Turpentine, crude, sp. gr. 0.900-0.970.....	gal. 1.75
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990.....	gal. .35
Pine wood creosote, ref.....	gal. .52

Naval Stores

The following prices are f.o.b. New York, for carload lots.

Rosin B-D, bbl.....	280 lb. \$13.00
Rosin E-F.....	280 lb. 13.10
Rosin G-N.....	280 lb. 13.15
Rosin W-G-W-W.....	280 lb. 13.25
Wood rosin, bbl.....	280 lb. 12.50
Spirits of turpentine.....	gal. 1.30
Wood turpentine, steam dist.....	gal. .
Wood turpentine, dist. dist.....	gal. .
Tar, kiln burned, bbl (500 lb.).....	500 lb. 14.50 - 15.00
Retort tar, bbl.....	500 lb. 15.00 - 15.50
Rosin oil, first run.....	gal. .72
Rosin oil, second run.....	gal. .75
Rosin oil, third run.....	gal. .92

Solvents

75-76 deg., steel bbls. (85 lb.).....	gal. \$0.40
70-72 deg., steel bbls. (85 lb.).....	gal. .38
68-70 deg., steel bbls. (85 lb.).....	gal. .37
V. M. and P. naphtha, steel bbls. (85 lb.).....	gal. .29

Crude Rubber

Para - Upriver fine.....	lb. \$0.26 - \$0.26 1/2
Upriver coarse.....	lb. .17 - .18
Upriver caucho ball.....	lb. .17 1/2 - .18 1/2
Plantation—First latex crepe.....	lb. .25
Ribbed smoked sheets.....	lb. .24
Brown crepe, thin, clean.....	lb. .22 1/2
Amber crepe No. 1.....	lb. .22

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls.....	lb. \$0.16 - \$0.18
Castor oil, AA, in bbls.....	lb. .17 - .17 1/2
China wood oil, in bbls. (f.o.b. Pac. coast).....	lb. .17 - .18
Cocanut oil, Ceylon grade, in bbls.....	lb. .15 - .16
Cocanut oil, Ceylon grade, in bbls (nominal).....	lb. .16 - .17 1/2
Corn oil, crude, in bbls.....	lb. .12 - .13
Cottonseed oil, crude (f.o.b. mill).....	lb. .10 1/2 - .11
Cottonseed oil, summer yellow.....	lb. .14 - .15
Cottonseed oil, winter yellow.....	lb. .
Linseed oil, raw, car lots (domestic).....	gal. 1.22 - .
Linseed oil, raw, tank cars (domestic).....	gal. 1.16 - .
Linseed oil, boiled, car lots (domestic).....	gal. 1.24 - .

Olive oil, commercial.....	gal	3 00	--	3 50
Palm, Lagos.....	lb	.10	--	—
Palm, bright red.....	lb	—	--	—
Palm, Niger.....	lb	.09	--	.10
Peanut oil, crude, tank cars (f.o.b. mill).....	lb	.10	--	.12
Peanut oil, refined, in bbls.....	lb	.17	--	.18
Rapeseed oil, refined in bbls.....	gal	1.30	--	1.45
Rapeseed oil, blown, in bbls.....	gal	1.60	--	1.70
Soya bean oil (Manchurian), in bbls N. Y.....	lb	.14	--	.14
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb	.10	--	.11

FISH

Winter pressed Menhaden.....	gal	\$0.85	--	\$0.90
Yellow bleached Menhaden.....	gal	.87	--	.90
White bleached Menhaden.....	gal	.90	--	.92
Blown Menhaden.....	gal	1.05	--	—

Structural Material

The following base prices per 100 lb. are for structural shapes 3 in. by 1/2 in. and larger, and plates 1/2 in. and heavier, from jobbers' warehouses in the cities named:

	New York			Cleveland			Chicago		
	Current	One Month Ago	One Year Ago	Current	One Year Ago	Current	Current	One Year Ago	Current
Structural shapes.....	\$4.58	\$4.47	\$3.47	\$5.00	\$3.37	\$4.08	\$3.47		
Soft steel bars.....	4.73	4.62	3.37	4.50	3.27	3.98	3.37		
Soft steel bar shapes.....	4.73	4.62	3.37	—	3.27	3.98	3.37		
Soft steel bands.....	6.43	6.32	4.07	6.25	—	—	—		
Plat. s, 1 to 1 in. thick.....	4.78	4.67	3.67	4.50	3.57	4.28	3.67		

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Connecticut

ANSONIA—The Amer. Brass Co., 58 Liberty St., will soon award the contract for the construction of a 1-story, 340x400 ft. addition to its factory. Estimated cost, \$700,000. Noted Sept. 22.

NEW BRITAIN—The Vulcan Iron Wks., 63 John St., has awarded the contract for the construction of a 1-story, 90x100-ft. foundry, to John Kung Co., 50 Green St. Estimated cost, between \$15,000 and \$50,000.

NEW HAVEN—The Connecticut Adamant Plaster Co., River St., plans to build a 2-story plaster plant. Estimated cost, \$150,000.

District of Columbia

WASHINGTON—The Bureau of Yards & Docks, Navy Dept., will receive bids until Oct. 15 for the construction of a 3-story, 60x200-ft. office and laboratory, 2-story, 82x300 ft. machine and testing shop, 1-story, 60x100-ft. foundry, etc. at the Naval Experiment Station at Beltsville.

Florida

WEST PALM BEACH (Palm Beach P. O.)—The State Bd. of Health, Jacksonville, will receive bids until Oct. 22 for the construction of a branch laboratory building here.

Illinois

CHICAGO—The Kroschell Bros. Ice Machine Co., 460 West Erie St., plans to build a new plant, including a machine shop, etc., on the south side of Diversey Ave., west of the St. Paul R.R. tracks.

Indiana

INDIANAPOLIS—The Link Belt Co., South Addison St. and the Big Four R.R., has awarded the contract for the construction of a 1-story factory on Belmont Ave. to W. P. Jungclauss, 825 Mass. Ave.

Iowa

FORT DODGE—The Bd. Educ. will receive bids until Oct. 27 for the construction of a 3-story, 190x260-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$650,000. P. E. Gustafson, secy. W. H. Htner, Bd. Educ. Bldg., St. Louis, Mo., archt.

Maryland

BALTIMORE—James J. Lacy Co., Philadelphia and Wells Sts., has awarded the contract for the construction of a foundry addition, to R. H. Mason, 308 West Madison St. Estimated cost, \$14,000.

BALTIMORE—The Natl. Bituminous Enamel & Paint Corp., Keyser Bldg., has awarded the contract for the construction of a paint and enamel plant, to the Price Constr. Co., Maryland Trust Bldg. Estimated cost, \$23,000.

CUMBERLAND—The Amer. Cellulose & Chemical Mfg. Co. plans to build an addition to its plant.

Massachusetts

WORCESTER—The Worcester Fdry. Co. Inc., 180 Prescott St., will build a 1-story, 60x150-ft. addition to its foundry on Prescott St. Estimated cost, \$30,000. Work will be done by day labor.

Minnesota

FRIDLEY—The Walsh Creosoting Co., St. Louis, Mo., plans to build a creosoting plant here. Estimated cost, \$200,000.

Missouri

CLAYTON—The city rejected all bids for the construction of sewers in sewer districts 1, 2 and 3. A septic tank will be installed in each. Work will be readvertised.

Nebraska

DANNEBROG—The Bd. Educ. is having plans prepared for the construction of a 2-story, 53x90 ft. school. A septic tank will be installed in same. Cost, between \$115,000 and \$120,000. W. Mape, Sheridan Bldg., Kansas City, Mo., archt.

MINATARE—The Great Western Sugar Co., Sugar Bldg., Denver, Col., will build a sugar factory to have a capacity of 1,200 tons of beets per day. Estimated cost, \$2,000,000. Work will be done by day labor. Noted Aug. 18.

New York

BROOKLYN—The Grand Corrugated Paper Co., 30 Crosby St., will soon award the contract for altering a factory on 32nd St. Estimated cost, \$50,000. P. Tilton & Son, 103 Park Ave., New York City, archt. and engs.

FORT NIAGARA—The Construction Dept., War Dept., Wash., D. C., plans to construct a filtration plant here. Estimated cost, \$25,000.

North Carolina

GASTONIA—The city has awarded the contract for the construction of a sewage disposal plant, to H. W. Harris, Durham. Estimated cost, \$60,000.

North Dakota

MARMARTH—The Bd. Educ. has awarded the contract for the construction of a 2-story, 61x91-ft. high school, to the Colewell-Long Co., 351 Plymouth Bldg., Minneapolis, Minn. A chemical laboratory will be installed in same. Estimated cost, about \$125,000. Noted Sept. 15.

Ohio

CLEVELAND HEIGHTS (Cleveland P. O.)—The Bd. Educ., Lee Rd., will receive bids until Oct. 20 for furnishing school building equipment, including chemical laboratory equipment, etc. Estimated cost, \$100,000. F. C. Warner, Hippodrome Annex Bldg., Cleveland, archt.

COLUMBUS—The Amer. Rolling Mill Co., Toledo & Ohio Central R.R., Parsons Ave., Columbus, O., has awarded the contract for the construction of an addition to its present plant, to Dwight P. Robinson, 125 East 46th St., New York City. Estimated cost, \$300,000.

Pennsylvania

PHILADELPHIA—Dill & Collins, Richmond and Tioga Sts., has awarded the contract for the construction of a 3-story, 28x58-ft. filter and pulp mill, on Manayunk St., to W. Steele & Sons Co., 16th and Arch Sts.

UNIONTOWN—The Uniontown Hospital will receive bids until Nov. 1 for the construction of a 3-story, 60x170-ft. hospital. A chemical laboratory will be installed in same. H. W. Altman, archt.

Tennessee

MEMPHIS—The Dixie Rubber Co. has awarded the contract for the construction of a 1-story, 75x290-ft. building to the Hydraulic Steelcraft Co., Hydraulic Ave., Cleveland, O.

Texas

DALLAS—The Trinity Paper Mills, 101 Marvin Bldg., and G. A. Beeman, Comanche, plans to construct three mills in Texas and will be in the market for equipment.

Wisconsin

FOND DU LAC—J. B. Fellrath, 180 North Main St., will build a 1- and 2-story, 70x120-ft. concrete block manufacturing plant on Brook Ave. Work will be done by day labor.

HORIZON—The Van Brunt Mfg. Co. will build a 1-story, 80x200-ft. foundry addition and a 40x80-ft. dry kiln. Work will be done by day labor.

MILWAUKEE—Backer & Pfaffler, archts., 216 West Water St., will soon award the

contract for the construction of a 1-story, 90x150-ft. factory on State St. for the manufacture of cement blocks, for the Shope Brick Co., 216 West Water St.

MILWAUKEE—The Modern Steel Casting Co., 1400 33rd St., plans to build a 1-story, 80x500-ft. or a 70x350-ft. foundry on 33rd St.

Quebec

MONTREAL—The governors of McGill University will have plans prepared for the construction of a biological laboratory, a modern pathological institute and a psychopathic hospital. Estimated cost, \$1,250,000.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1920 meeting Dec. 27, 1920, to Jan. 1, 1921, at Chicago, Ill.

AMERICAN CERAMIC SOCIETY will hold its annual meeting the week of Feb. 21, 1921, at Columbus, Ohio, with headquarters at the Descher Hotel.

AMERICAN ENGINEERING COUNCIL of the Federated American Engineering Societies will hold a meeting Nov. 18 and 19, 1920, in Washington, D. C. Headquarters will be at the New Willard Hotel.

AMERICAN MINING CONGRESS will hold its next convention in Denver Nov. 15 to 19.

AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS' 1920 annual meeting will be held in the Engineering Societies' Building from Dec. 7 to 10 inclusive.

CANADIAN INSTITUTE OF MINING AND METALLURGY will hold its second annual Western meeting in Winnipeg, Man., on Oct. 25, 26 and 27. Headquarters will be at the Hotel Fort Garry.

ENGINEERING COUNCIL will hold its next meeting in Chicago, Thursday, Oct. 21.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall national convention at Carnegie Music Hall, Pittsburgh, Pa., Nov. 10, 11 and 12.

Industrial Notes

THE C. & G. COOPER CO., of Mt. Vernon, O., at the regular June directors' meeting, elected B. B. Williams president of the company to succeed D. B. Kirk, deceased; F. H. Thomas was elected vice-president to succeed Mr. Williams and N. L. Daney was elected treasurer to succeed Mr. Thomas. The Chapman Engineering Co., the Chapman-Stein Furnace Co., and the Marion Die, Tool & Machine Co., with its well-equipped plant at Marion, O., are subsidiaries of the Cooper company. The complete service of the combined companies therefore now includes not only the Cooper gas engines and Cooper Corliss engines, it covers also Chapman gas producers and Chapman-Stein furnaces. This complete combustion engineering service enters practically every line of industry which utilizes gas for power or for industrial heat.

THE OXWELD ACETYLENE CO., New York City, has established Pacific Coast sales and distributing headquarters at San Francisco, with offices at 1077 Mission St. This company also announces that the export department, which was formerly located at the company's factory in Newark, N. J., has been removed to the Carbide and Carbon Bldg., 30 East 42d St., New York. The department has been reorganized and is now under the direction of R. G. Noble, who will co-operate with the general sales department of the company.

D. M. LUBELL announces the removal of his offices to 2 Rector St., New York City.

DICKS-DAVID & CO., of New York, and **DICKS, DAVID & HELLER**, of Chicago, manufacturers of dyes and intermediates, have consolidated into one firm under the name of the former.

DR. ROBERT P. FISCHER, consulting chemist, of Philadelphia, has removed his business office to the Foster Bldg., 280 Madison Ave. (corner 10th St.), New York City. He is specializing on investigations of markets and sources of supply for chemical, pharmaceutical and biological products.

and the preparation of scientific and commercial literature along chemical, pharmaceutical and medical lines. Dr. Fischelis will continue as a member of the faculty of the Philadelphia College of Pharmacy and as director of the technical department of the Matos Advertising Co., of Philadelphia. He has also been retained by the National Research Council to assist in securing the support of the chemical industries in the matter of publishing an American volume of critical tables of physical and chemical constants.

OLIVER CONTINUOUS FILTER CO., manufacturer of the Oliver Continuous Filter, dry vacuum pumps, air compressors, centrifugal pumps, etc., has appointed J. F. Mitchell-Roberts as its special representative in England and Europe. Offices have been established at No. 2 Broad St. Place, London, E. C. 2, England. In connection with its offices at 33 West 42d St., New York, and 502 Market St., San Francisco, Cal., this company maintains laboratories for investigation of filtration problems and similar arrangements will be made at its new London office.

WHITING FOUNDRY EQUIPMENT CO., of Harvey, Ill., and the AMERICAN FOUNDRY EQUIPMENT CO., of New York, consolidated to form the Whiting Corporation, capitalized at \$5,000,000. J. H. Whiting becomes chairman of the board and V. E. Minch president of the company. The Whiting plant at Harvey will retain the manufacture of cranes, cupolas, hoists, mills, core ovens and all other items of the established Whiting line, together with sand-blast equipment and dust arresters. Sand-cutting machines and steel castings will comprise the bulk of the work at the new American plant at 2925 West 47th St., Chicago, under the direction of E. A. Rich, Jr. Molding machines, jolts, slabs, specialties and pattern-mounting materials will continue to be manufactured at the York, Pa., plant of the American company in charge of H. S. Rich.

THE MIDWEST ENGINE CO. has sent its exhibit which was at the National Exposition of Chemical Industries to the office of Charles F. Ames & Co., Ltd., 90 West St., New York.

FRANK LABORATORIES FOR CHEMICAL INDUSTRY, San Francisco, announces the beginning of work on a new chemical factory in Oakland, Cal., on Oct. 1, for the production of organic chemicals from crude oil tars and shale oil.

CHARLES PIEZ, president of the Link-Belt Co. and former director general of the Emergency Fleet Corp., has written a report on the steel strike. Copies of the article can be secured by applying to the executive offices of the Link-Belt Co., 910 South Michigan Ave., Chicago, Ill.

WILEY & Co. announces the removal of its laboratory and offices to the northwest corner of Calvert & Read Sts., Baltimore, Maryland.

INDEPENDENT CHEMICAL CO., INC., of Hartford, Conn., has recently been organized and incorporated with a capital stock of \$25,000, to engage in manufacturing chemicals, etc. Further information can be secured from M. A. Fierberg, 16 Westland St., Hartford, Conn.

THE PETROLEUM RECTIFYING CO. OF CALIFORNIA announces the engagement of the services of Sanderson & Porter, consulting engineers, to supervise research work and the development of apparatus and equipment for the dehydrating of petroleum emulsions by the electric process. The basic Cottrell patents controlled by the company have recently been adjudicated by the United States Supreme Court. It is now proposed to further develop the apparatus with the view of increasing the capacity and efficiency.

DWIGHT P. ROBINSON & Co., Inc. (with which Westinghouse, Church, Kerr & Co., Inc. has recently consolidated), engineer and constructor, of New York, has established a new branch office in Youngstown, O., in the Home Savings & Loan Bldg., in charge of C. L. Crippen. The company recently moved its Cleveland office from the Leader-News Bldg. to the Citizens' Bldg., and H. P. Clawson, who was for several years a member of the Chicago staff, has been transferred to Cleveland to take charge of this office. The company now maintains branch offices in Pittsburgh, Youngstown, Cleveland, Chicago, Dallas and Los Angeles, and Sao Paulo, Brazil.

STANDARDIZATION COMMITTEE OF THE NATIONAL ASSOCIATION OF PURCHASING AGENTS considered four problems at its meeting at Chicago Oct. 9. They were: Standardization of catalogs; standardization of invoices; pricing on a decimal basis; standardizing shuffling uses.

Manufacturers' Catalogs

QUIGLEY FURNACE SPECIALTIES CO., New York, is distributing a new booklet on "Hytempite in the Gas Plant." This 16-page booklet contains illustrations showing how Hytempite serves, and how the life of brick work is increased by proper bonding of refractories, also Hytempite in the gas plant, laying firebrick and tile, in gas generators, flue linings and valves, for patches and repair work, the spraying of Hytempite for filling cracks, coating walls and other brickwork, sealing coke oven jamb joints, gas producer linings and for industrial gas fired furnaces.

THE MERRILL CO., San Francisco, Cal., has issued a booklet on the Nordstrom Lubricated Plug Valve.

MAURICE A. KNIGHT, East Akron, O., has issued a folder which, although it is not a full catalog or a complete list of what he manufactures, is a guide to the possibilities of design of acid-proof chemical stoneware apparatus, which can be made in any shape or design mechanically possible. In this folder are various explanatory and instructive articles on the subject of chemical stoneware, its uses and limitations.

UEHLING INSTRUMENT CO., 71 Broadway, New York, has just issued Bull. No. 111 describing Style U Uehling CO₂ equipment. This is a new design built in single and multiple forms, the latter serving any number of steam boilers simultaneously up to a total of six. The purpose of this equipment is to save fuel by burning it with the proper air supply. Among the notable features of the new machine are speedy action, resulting from a new form of aspirator, absence of chemical solutions, greater simplicity and the unique plan of providing an auxiliary boiler front CO₂ indicator, which guides the fireman, while the CO₂ recorder, installed in the chief engineer's or superintendent's office, makes a continuous (not intermittent) record, showing all changes in boiler adjustments that are conducive to either waste or economy.

THE WESTERN REINFORCED CONCRETE PIPE CO., Los Angeles, Cal., calls attention to a catalog on Reinforced Concrete Pipe. In this book is pointed out the unique adaptability of reinforced concrete pipe for sewers, storm drains, culverts, pressure lines and irrigation systems. Many interesting illustrations are given together with descriptions and letters from users.

PYROELECTRIC INSTRUMENT CO., Trenton, N. J., has issued Bull. 14, which contains an article on hydrogen ion determinations, together with descriptive apparatus and notes on technical applications of the methods.

ALBERGER CHEMICAL MACHINERY CO., Grand Central Palace, New York City, has just published several booklets. One folder describes Agitator Drives for stirring, mixing, agitating, dissolving and digesting, while Bull. 26, also on Alberger Agitator Drives, describes the six sizes of bevel gear drives and six sizes of worm gear drives, together with several designs of stirrers, which are illustrated. Bull. 28, on Chemical Apparatus, illustrates and describes autoclaves, nitrators, heat exchangers, sulfonators, mixing kettles and digestors.

GRISCOM-RUSSELL CO., New York, has issued Bull. 260, on the Kelly Water Heater. Many interesting types of this multifuel heater are illustrated and described.

THE SMITH GAS ENGINEERING CO., Dayton, O., is distributing Bull. 16, on the Smith Type "G" Gas Producer, which produces cold clean producer gas for power and industrial heating. Typical gas analyses are given, together with the design of the producer, the process of gas production, the rating, the practical uses for Smith cold clean producer gas and the Smith recording gas calorimeter.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING CO., East Pittsburgh, Pa., has issued leaflet 3461, which describes and illustrates its automatic current regulator for electric arc furnaces with movable electrodes. Schematic wiring diagrams and photographs of detailed parts of this apparatus are produced.

THE BUFFALO FORGE CO., Buffalo, N. Y., has published an attractive catalog, No. 460, on Buffalo Standard Heaters. The catalog has been prepared with the view of making it most useful to architects and engineers in figuring the heater requirement for fan heating and ventilating work. The tables

have been elaborated so as to include all the conditions usually met with in practice and to enable the user to read the values direct. To meet unusual conditions curves have been added which give values for various steam pressures and air velocities, and these enable any condition to be readily taken care of.

THE AMERICAN TOOL & MACHINE CO., Boston, Mass., has issued a catalog on Weston centrifugals for sugar-chemicals. Many illustrations and descriptive matter are given of the different types, together with a section on sprayers, dischargers, perforated linings and bakings. There is also a very interesting write-up on scientific sugar washing. The booklet has been published in Spanish as well as in English.

THE ELECTRIC FURNACE CO., Alliance, O., is distributing Bull. 9-B, which illustrates and describes Bally electric furnaces for melting non-ferrous metals, also for heat treating and annealing.

THE LINK-BELT CO., Chicago, Ill., is now ready to distribute its 32-page book, No. 345, entitled "Link-Belt Silent Chain Drive for Cement Mill Equipment," which should be of advantage to engineers, superintendents and other officials of cement mills. This company has also published an engineering data book on the Link-Belt Roller Chain. This 78-page book, No. 257, shows photographs of roller chain drives operating motor trucks, tractors, cotton gins, industrial locomotives and other equipment. It is a handbook of value to power transmission engineers, and contains tables from which the proper size of chain and sprocket wheel can be selected to result in the best driving arrangement. This company also calls attention to the revised edition of catalog 380, which is now off the press and available for distribution. This 96-page book covers the Link-Belt line of standardized monorail electric hoists, as well as overhead electric traveling cranes in capacities of 4 to 3 tons inclusive. It completely describes these machines, giving tables of weights, clearance dimensions and speeds, together with illustrations, which include photographs of machines in operation.

ACHEMSON GRAPHITE CO., Niagara Falls, N. Y., announces a new publication on Brass Melting. This booklet presents information in regard to the electric melting of non-ferrous metals which is based upon statements by leading engineers of the industry and upon articles appearing in trade periodicals and the proceedings of technical societies. Short descriptions of various designs of arc and resistance furnaces have been contributed by the makers and are given in their own words.

HARDER-GREENE CO., Aurora, Ill., announces a new catalog, No. 1, on B-G Standardized Material Handling Machines, which consist of self-feeding bucket loaders, portable belt conveyors, and permanent belt conveyors for the handling of all kinds of bulk material. Many interesting illustrations are given, together with descriptive matter.

VICK, BLACKWELL & BUCK, New York, has published Bull. 11, on Acids. This bulletin is an attempt to set up in convenient form descriptions of the acids which constitute a very large proportion of those commercially manufactured and exported, together with mention of a few of the principal uses of each of the acids in order to assist foreign purchasers in the development of business.

CUTLER-HAMMER MANUFACTURING CO., Milwaukee, Wis., has issued five new booklets on: The Value of Accurate Measurements of Gases and Air; Electric Heating of Water; Charging Equipment for Miner's Lamp Batteries; Metal Melting Pots; Battery Charging Equipment.

ARMSTRONG CORK & INSULATING CO., Pittsburgh, Pa., has published two booklets. "Armstrong's Cork Tile" gives illustrations and descriptions of tile suitable for banks, offices, libraries, museums, residences, stores, hotels, etc. The other booklet describes "Linotile Floors," suitable for offices, churches, banks, libraries, kitchens, pantries, theatres, stores, museums, elevators, sun rooms, etc. Many interesting illustrations are given in color, showing actual floors of Linotile. Anyone interested in flooring materials will be furnished copies upon request.

E. I. DU PONT DE NEMOURS & Co., Wilmington, Del., has published an attractive booklet on Dyestuff Intermediates.

NORTON CO., Worcester, Mass., has published a booklet on Snagging, which deals with the selection, care and use of snagging wheels.

The Long Road to Scientific Control

THERE has been organized a Canadian Society of Technical Agriculturists at Ottawa, and at the first convention, held in June, Professor W. P. THOMPSON, of the University of Saskatchewan, addressed the members on Scientific Research in Relation to Agricultural Problems. The address was printed in the October 1 number of *Science*.

The purpose of the association is to foster and develop the application of science to agricultural industry. The difficulties are many, despite the immense efforts that have been made, both here and abroad, to make of farming a real profession. The public at large, as Professor THOMPSON points out, thinks chemistry, for instance, a highly complex and mysterious study, capable of performing all sorts of wonders, whereas nearly every one thinks he understands agricultural operations. Now agricultural problems are as complex as those of any other industry, and progress is possible only through the application of scientific facts and principles by those who have been properly trained. The scope of necessary research is no less than immense. It involves the physics, chemistry, biology and geology of the soil, physiology and pathology of both plants and animals, systematic biology, entomology, foreign plant introduction, genetics, bacteriology, mechanics, climatology, sociology and economics. It makes the operation of a blast furnace, for instance, look like a scientific toy; and nobody complains that the operation of a blast furnace is too easy. There is so much to do, or to put it a little differently and yet to mean the same thing, our present ignorance is so general and all-encompassing that a mere list of the sciences involved looks impractical. It certainly is enough to frighten anybody who owns a farm.

Nevertheless, the benefits which already accrue as the result of research in agriculture are not surpassed by those of any other industry, although the real study is hardly more than begun. The day may come within the next generation when some other method of settling labor difficulties will take the place of the strike, and as soon as this happens industrial, large-scale farming with its own warehouses, its villages, its transportation systems for labor, etc., will probably become profitable, because scientific control, properly applied, always pays. And scientific control in farming involves the co-ordination of many trained minds.

In the meantime other industries less complex in their nature and requirements had better provide for scientific control—or else look for the road that leads into the tall timber. Who would now undertake to produce iron from ore with an old furnace doctor to judge materials by “the look of them” and to dose the furnace with secret medicines when trouble appears? Where will the auto-

motive industry be unless more liquid fuel of the right kind is developed to operate the engines? But cracking petroleum is a simple problem compared with the long list of things yet to be done on the farm. The rubber industry has made a start. Some tanners, but far from all, have begun to see the light. A few iron founders are scientific, but more are not. Only a few years ago makers of brass were enlightened by Egyptian traditions, and they had little inspiration of later date. A large part of the ceramic industries is still operated under the rule of thumb. The enlightenment of science in industry is only beginning; just beginning.

Metallic Oxides Soluble in Steel

WHILE a great deal of the space occupied by Messrs. RAWDON, GROESBECK and JORDAN in this issue is devoted to a study of nitrides in arc-welded iron, one very suggestive remark about oxides is made which may be worthy of rather more emphasis. Following MILLER and COMSTOCK, the present authors have labeled “oxide” the small rounded spots occurring in the micrographs, which spots, by the way, are identical in appearance with those in vacuum-fused electrolytic iron of high purity, but oxidized on the surface before melting. Whether the spots are FeO —a compound whose very existence is questioned—higher oxides of iron or more complex mixtures of various metallic oxides and silicates is not known, nor can such problems be solved without much more experimental information than is available at present.

The notable fact developed by our present contributors, however, is this: That whenever arc-fused iron was heated to 1,000 deg. C. in a relatively high vacuum for several hours there resulted a great decrease in the number of small rounded inclusions originally present, together with a marked increase in size of the still remaining ones. Here is the first instance coming to attention of the migration of non-metallic inclusions. As pointed out recently in these columns, no one ever has affirmed such movements, and many have testified they have looked for it without avail. WHITELEY, at the fall meeting of the British Iron and Steel Institute, in vainly attempting to remove deep-seated oxide spots from ingot iron by annealing in hydrogen, says: “No indication of such migration [of oxide inclusions to the surface] occurring to any appreciable extent was observed in a strip after it had been heated *in vacuo* for three hours at 1,050 deg. C.” Yet RAWDON and his collaborators present undoubted evidence of changes in the disposition of insoluble oxidized inclusions. Such movement, we take it, involves a certain solubility of the oxidized particle in the hot solid metal. The authors

do not agree to this inference, but their view expressed in correspondence, that "during the agglomeration of the originally small ferrite grains during the stay above A_1 , the oxide inclusions in the various and adjoining small ferrite grains were in some unexplained manner brought together to form a single and larger inclusion," appears to be only another way of saying that the grains were observed to be larger after heating. MAHIN'S work also has a tendency to show that non-metallic inclusions are slightly soluble in solid ferrite.

Oxygen has popularly been held to be of utmost danger to sound steel. Volumes have been written about refining operations in bessemer and open-hearth, and about blowholes and dead-melted steel, much of which involves the ultimate assumption of the presence of quantities of oxide in the metal. Yet ROSENHAIN says that it is extremely doubtful whether iron oxide is soluble in molten iron—notable constancy of results which various investigators have reported for the melting point of pure iron is strong support of this idea. In this connection it may be noted that evidence of the insolubility of FeO in liquid iron is pretty good evidence of insolubility at lower temperatures because of the well-established rule that "solubility decreases with lowering temperature."

It is quite unfortunate that we have no precise quantitative method for determination of oxygen in steel, and our knowledge of the nature of non-metallic inclusions is but scanty, consequently it has been possible to infer that iron oxide is insoluble in solid metal only from the fact that oxidized inclusions are unaffected by ordinary heat treatments. Yet several recent researches, including the one printed in this number of CHEMICAL & METALLURGICAL ENGINEERING, have thrown doubt upon this popular supposition.

Thus, HUMPHREY found that pure iron heated in air acquired a superficial layer of oxide but apparently was not otherwise affected. If the oxygen pressure was reduced to less than 10 cm. the surface was oxidized only in spots after annealing at 1,000 deg. C., yet the piece acquired great intercrystalline brittleness, a defect which could be cured by annealing in hydrogen, or by heating above A_1 and quenching. To explain these facts he assumed two kinds of oxides—the ordinary scale, which is insoluble, and an embrittling sub-oxide, which collects at the grain boundaries—even though invisible under the microscope—and which is soluble in gamma iron. MILLER explains the brittleness of fusion welds and its cure by a reducing anneal, by the same "invisible oxides." LE CHATELIER and ROGITCH more recently maintain that the macrostructure revealed by STEAD'S reagent is due to oxygen distribution rather than phosphorus, while MCCANCE goes further and ascribes the micro-ghost lines to oxygen, since this appearance can be destroyed by hydrogen at 1,000 to 1,100 deg. C. (supposedly without difficulty), yet the phosphorus analysis shows no difference. WHITELEY has also proved that micro-ghost lines persist in areas where uniform distribution of phosphorus has been attained, and therefore must be due to some other substance which diffuses with extreme slowness at temperatures below 950 deg. C.

These researches all appear to indicate that there is one extremely tenuous and extremely dangerous oxide commonly observed in steels, besides the well-known and relatively less harmful particles of scale, slag or mixed reaction products. The latter seem to be

reduced to metal with extreme difficulty by a hydrogen anneal, while the former, either by reason of its existence in solid solution or by reason of a different composition, reacts much more readily with occluded hydrogen. Under certain circumstances the insoluble oxide apparently may pass into a soluble modification and again revert to insolubility.

Even though one might disagree with MCCANCE that much of the bad reputation of sulphur and phosphorus is due to FeO in the steel, and with GIOLITTI that the phenomenon of transverse fragility is largely enhanced by oxidized inclusions in the steel, it behooves all of us to turn our attention to the many unsolved problems collateral with this recently raised query regarding soluble metallic oxides in steel, their origin and prevention, their effect and cure.

A Thermal Flow Sheet

IN CERTAIN industrial operations it is common to strike a weight balance and a heat balance at appropriate intervals in order to check up on otherwise unsuspected losses. However, this program apparently is not as widely followed in chemical industry as is desirable. If every source of energy is taken into consideration, and the ways in which this energy is used or dissipated ineffectively are recorded regularly, means are often suggested for correcting losses that have not previously been noted.

One can take as an excellent example of the need of thermal analysis the problems connected with the coking of a ton of bituminous coal with production of coke and byproducts. The figures reported recently on the coking of Illinois coal illustrate the importance of this problem. Two thousand pounds of this material averaging 12,500 B.t.u. per pound gives 25,000,000 heat units to account for. Approximately 1,400 pounds of coke of a heating value of about 11,000 B.t.u. per pound accounts for approximately 62 per cent of the original heat available, or, to be exact, 15,400,000 B.t.u. The five and one-half "M" of surplus gas formed would account for approximately 3,100,000 B.t.u. The eight gallons of tar averaging perhaps 140,000 B.t.u. per gallon represents $4\frac{1}{2}$ per cent of the original heat, or, roughly, 1,100,000 B.t.u. Slightly less than four gallons of light oil having about 135,000 B.t.u. per gallon represents 2 per cent more of the original heat, or a little over 500,000 B.t.u. In these products and the ammonia we find about 85 per cent of the heat originally in the coal. The remainder has been consumed in the processes. To be exact, the test referred to showed that 1,430 B.t.u. was used for the coking of each pound of coal as charged to the battery. The analysis of heat dissipated by radiation from the battery, sensible heat in the gas, sensible heat in the coke as pushed from the oven, and heat carried off in the flue gases from the heating chambers of the ovens would be very enlightening to show what has become of this amount of heat, which represents more than 10 per cent of the total originally available. To a certain extent such analyses have been made, but by no means as many such studies of the industrial processes in general have been accomplished as would seem to be well worth while.

Energy these days costs too much money to waste, even if purchased in the form of the cheapest bituminous coal. The chemist, being thoroughly familiar with the physical changes and thermal relations of various stages of the process, may well apply himself to problems like

this. In any industry that is well standardized, the variations in process are often most clearly pointed out by such study. In new industries means for improvement in efficiency are quickly discovered. In other words, no matter in what stage the industry may be, the thermal study will be well worth while.

In such a study, however, great accuracy may not usually be possible. This, however, is no excuse for omitting attention to the subject. We need more data as to heat conductivity and heat capacity of materials of construction as well as for materials entering into the processes themselves. Without such data an accurate analysis of heat utilization and wastes can, of course, not generally be made. Conditions in this respect are, however, continually improving and increased attention to the application of thermal chemistry will accelerate our investigations of thermal data quite to the advantage of both the industry and the investigations.

Steel Production And Processes

THE steel production statistics for 1919, just made public by the American Iron and Steel Institute, furnish some interesting information as to the vogue of the various producing processes. The amount of production as a whole has been fairly well known since the end of the year through the medium of trade estimates. The output of ingots was 33,694,795 tons, against the record output of 43,619,200 tons, in 1917, and against a capacity that may be estimated at about 52,500,000 tons, which is 50 per cent above the estimated capacity in 1914, when the war began. Thus the output was only about 64 per cent of capacity, but at that it was 11 per cent in excess of the output in 1912 and 1913, the two best tonnage years before the war.

The output of steel castings did not make as good a showing as the ingot output, being 976,437 tons in 1919, against 1,441,407 tons in the record year of 1917 and 1,020,744 tons in 1913, the best year before the war.

The output of rolled material amounted to 24,042,093 tons of rolled steel and 1,059,451 tons of rolled iron, making a total of 25,101,544 tons. The output of rolled iron was the smallest for many years, and was only half the output in 1905, 1906 and 1907, when the wrought iron industry experienced a redivivus. It was about the year 1892 that the production of wrought iron began to decline, there having been growth previously even though the new material, "soft" steel or "mild" steel as it was then generally called, was making great inroads.

The proportion of rolled steel to steel ingot production has undergone some interesting changes. The percentage has been as follows:

1908	77.5	1911	75.1
1909	77.0	1915	70.2
1910	79.9	1916	73.8
1911	76.3	1917	71.6
1912	76.0	1918	68.6
1913	76.1	1919	71.5

A mere scrutiny of the table would suggest that American steel manufacturers have grown progressively more wasteful, producing more scrap and scale before arriving at the finished rolled material. For the earlier years in the table it is to be remarked, however, that previous to 1912 the semi-finished steel

exported was not ascertained and thus some steel was lost in the statistics, though there was no pecuniary loss to the works. The drop in the percentage during the war years was doubtless caused by the heavy cropping involved in the manufacture of shell steel, and this influence appeared in the production of steel for forged shells, since rolled forging blooms and billets are reported as rolled steel output. As for the low percentage in 1919, that is doubtless to be attributed to labor inefficiency. A return to approximately a 76 per cent proportion is to be expected.

The vogue of the duplex process has not increased as much as was expected. The tonnage of "duplex" steel reported, as part of the basic open-hearth output of steel ingots and castings, and the percentage the tonnage comprised of the total basic open-hearth steel output, are shown below:

	Duplex, tons	Percentage
1912	1,438,654	7.3
1913	2,210,718	11.4
1914	835,690	5.1
1915	1,781,491	8.0
1916	3,436,457	11.6
1917	3,791,830	11.8
1918	3,870,017	11.9
1919	3,819,785	11.0

If, however, the steel works had had as much difficulty in the past few years in securing scrap as it was predicted years ago would be the case, there would have been much more employment of the duplex process than is shown, for 11 per cent is no high proportion for the duplex process.

Electric steel makes an excellent showing for 1919, the production, in ingots and castings together, being 384,452 tons, this being the largest output on record outside the 511,364 tons produced in 1918, largely against certain special war requirements.

Two Hundred Academic Ambassadors

GERMANY is planning to continue her ante-bellum practice of exporting scientists stamped with the familiar mark "Made in Germany." Dr. CHARLES SOLF, after ninety days of Ambassadorship in Japan, has established cordial relations and obtained an invitation from Marquis OKUMA for two hundred Herr Doktors to spend their time in Japan, each receiving \$10,000 per annum. Two million a year is said to be cheap for the service Japan expects to receive. Half of the Ph.D.'s will be placed in the universities. The others will be engaged in industrial research and development work.

Conditions in Germany are without doubt bad. Many eminent scientists and engineers there cannot obtain remunerative occupation and must emigrate either from their profession or from their country. By going to Japan under the able leadership of Dr. SOLF they can escape the first alternative and technically avoid the second. They will be part of the German Embassy, so to speak, and will function with due regard to the rules of Berlin diplomacy. The doctrine of German supremacy will be taught first, last and always. Science will be gesprochen und gelesen while Kultur is taking root. Japan may get her two million dollars worth of science yearly but if she has to pay the price of subjection to a foreign leader in scientific thought in addition she will be the loser. However, all other nations will owe her a debt of gratitude for harboring this horde of academic ambassadors, for they certainly will build an undesirable propaganda system wherever they go.

Notes on French Industries

FROM OUR PARIS CORRESPONDENT

Paris, France, September 15, 1920.

THE industrial situation in France will continue to be precarious as long as the coal question is unsolved.

Before 1914 France had to depend on import for 40 per cent of the needed fuel; today its dependence is more accentuated due to the destruction during the war of the greater part of the coal mines in the fighting regions. France needs now annually at least 76,000,000 tons, this being the tonnage used during 1913. As the country is expected to produce only 24,500,000 tons, the remaining 51,600,000 tons—i.e., more than 73 per cent of the fuel needed—must be imported. With Germany supplying 19,000,000 tons, Great Britain, United States and Belgium about 15,000,000 tons and 5,000,000 tons from the Saar district, France will have only 63,500,000 tons instead of the 76,000,000 tons needed. The deficit of 12,500,000 tons works great hardship especially on the chemical and metallurgical industries. It is hoped that the government will find a way to remedy this shortage of coal.

HYDRO-ELECTRIC INDUSTRY

The chemists and metallurgists have great hopes that the development of the French hydro-electric power will alleviate the fuel shortage. It is estimated that one hydro-electric horsepower is equivalent to five tons of coal. The country is very rich in waterfalls, especially in the regions of the Alps and Pyrenees. It is estimated that there is available 10,000,000 hp., of which 5,000,000 might be used for the industries. Of this only 2,550,000 hp.—i.e., 1,800,000 kw.—will be in use when all the work now under construction is completed. This figure could easily be doubled if the government would do its share to facilitate development by according concessions and hastening the reclaiming work.

It is safe to state that the present investment in the French hydro-electric industry amounts to over one billion francs. Further water-power developments require vast capital, especially when it is considered that instead of the 500 to 800 fr. pre-war cost per horsepower developed, the post-war cost is from 1,000 to 1,600 fr. Money is not scarce in the country, but the French capitalists are timid and not enterprising. They prefer to stick to the old custom of keeping the greater part of their wealth in cash and investing the remainder in bonds and shares securing them a fixed revenue. It is also a fact that the farmers have grown rich during the war and still continue to grow rich. The French farmer working his small piece of land by the rudimentary methods of a hundred years ago earns enough and does not care to become interested in the industry of the country and in the resulting progress in agriculture.

ALSATIAN POTASH

The annexation of Alsace resulted in France having now the petroleum it needs from the Pechelbrom oil field and the rich potash mines of the Mulhouse district. The potash lies at a depth of about 600 m. in two seams, one of an average thickness of 3.5 m. (about 11 ft.), the other of about 1 m. (about 3 ft.). It is estimated that there is a reserve of 300,000,000 tons of pure potash. Unfortunately the working of the mines was not

as active as it ought to have been, due to the difficulties resulting from the uncertainty as to the definite allotments of the mines. The solution lately arrived at is the buying of the mines by the French Government and the leasing to responsible persons or concerns. The government paid 150,000,000 fr., but this sum is simply to mark the entrance in possession; the real value of the mines is estimated to be between two and three billion francs. The leasers, it would seem, will have to abide—in a certain degree at least—by the desiderata formulated by the workmen for the nationalization of the mines. It is to be hoped that the French administration will not lose much time in placing the mines in actual and extensive working order.

SYNTHETIC AMMONIA

Up-to-date agriculture would afford a great market for synthetic ammonia. Georges Claude is working now on its production by a process differing from that of Haber in that he uses 1,000 atm. pressure instead of Haber's 200. France requires yearly about 100,000 tons of ammonium sulphate.

THE FRENCH DYESTUFF INDUSTRY

The Compagnie Nationale des Matières Colorantes, founded with the moral support of the French Government, which has put at the disposal of the company the powder plant of Oissel (near Rouen), for the first time since its foundation in 1917 has declared a 5 per cent dividend. The company, with which is consolidated the Société des Colorants Français, is now capitalized at 71,000,000 fr.

The most important product manufactured by the company is synthetic indigo, the production being more than 200 tons per month, of which a great part is exported to the United States.

Other products manufactured are direct cotton dyes and acid dyes for wool, and sulphur dyes. The company is working on a program for the manufacture of basic and anthraquinone dyes. It is expected that this program will be in working order by 1921.

The total production of the French plants of various dyes is at present about 600 tons per month, say in round figures about 7,000 tons per year. The French consumption, including that of Alsace and Lorraine, is estimated to be 12,000 tons per year; this shows that much is still to be done in the dye industry to make the country independent of foreign dye products.

The French manufacturers are directing their activities toward the production of special dyes.

Coal and Coke Production in the Saar District During the First Half of 1920

The production of the Saar mines during the first half of 1920 is given in the following table:

	Coal, Metric Tons	Coke, Metric Tons
January	727,465	18,224
February	743,083	18,292
March	839,874	20,141
April	734,685	19,099
May	709,766	18,571
June	763,616	19,676

At the end of June the entire personnel consisted of 69,056 miners and 2,573 engineers and other employees. The net production of coal per man per day reached 470 kg. (about 1,030 lb.).—*Echo des Mines et de la Métallurgie*, Sept. 10, 1920.

Foundrymen and Institute of Metals Meeting

Reports on Papers Presented at the Columbus, Ohio, Annual Joint Meeting of the American Foundrymen's Association and Institute of Metals Division of the Mining and Metallurgical Engineers

THE American Foundrymen's Association and Institute of Metals Division of the Mining and Metallurgical Engineers held their annual joint meeting in Columbus, Ohio, Oct. 4 to 8. As is their custom, an exhibit of foundry equipment was also held at the same place, occupying seven of the group of permanent buildings erected on the State Fair Grounds. As pointed out by the president in his annual address, it has rapidly become a problem how to handle this very desirable adjunct to the annual meeting. There is a constantly growing number of applications for space, and it does not seem possible to restrict the amount allotted to each exhibitor. It is the policy of the organization to hold the general meetings in different cities, so that every so often a meeting is held in each section of the country, yet there are few cities which have the necessary exhibition space for a show such as the Foundrymen now stage. Or, given the exhibition space, hotel accommodation for the large number of visitors may not be available, as indeed was the case at Columbus. Lucky were they who were accepted by a hotel—those who came from a distance and wished to stay for more than a day had to scurry around town for accommodation in a private residence.

Simultaneous sessions of the two main organizations, with a meeting of the Electric Furnace Association and a continuous performance at the exhibit, made it rather hard for the man in attendance to be in as many places as he would like. On page 769 of this issue will be found the proceedings of the Electric Furnace Association. Hereafter will be given notes on several papers appearing before the Foundrymen and Institute—subsequently also we hope to give a full account of a very interesting session on Malleable Iron. Little mention will be now made of some important papers read before a session devoted to metallography and general subjects, reserving them for presentation in future issues.

In general, it may be said that the technical sessions were well up to their previous high standard, and in many respects excelled. Particularly noticeable was the large attendance of interested men at all the meetings. As a guarantee of continued improvement in the quality of its transactions, announcement was made at the banquet of the establishment of a fund of \$21,000, presented to the Foundrymen's Association by five donors, the income of which is to be awarded to the authors of the best contributions on certain phases of the industry.

Social events of the sort which have come to be expected of the annual event—plant visitation, golf tournament, smoker and banquet—were enjoyed by the members journeying to Columbus. Unfortunately, however, it is a Presidential year, and the committee on arrangements seemed to have forgotten that all who must listen to the speeches might not be of their political faith!

Meeting, American Foundrymen's Association

THE opening session of the American Foundrymen's Association was to receive a number of papers on Gray Iron, but after reading his short paper giving a few experiments using 30 per cent ferrozirconium as a deoxidizer, the meeting became a class in elementary principles of cupola practice, with Dr. Moldenke as instructor, even continuing all afternoon. All his ideas radiated from a main thesis that there were three essentials in good foundry practice, neglect of any one being fatal to the final result. First, one must start with good materials; second, melting practice must be correct; and third, proper gating of the molds must be provided. Defects not obviously due to slovenly workmanship could always be traced to one of these three steps.

George K. Elliott, of the Lunkenheimer Co., presented a brief note drawn from his experience in refining cupola-melted iron under a carbide slag in a basic electric furnace. Sulphur may be reduced from 0.13 to 0.05 in from forty minutes to one hour, depending upon the condition of the slag and the furnace atmosphere. Cost is largely for electricity. Current consumption in such a run would be from 200 to 350 kw.-hr., depending upon the time and superheat required, and the entire cost would range from 1c. to 1c. per lb. iron. In return for this, the castings, especially if small, machine easier with a large decrease in defectives; transverse test bars are 50 per cent stronger (tensile tests about the same); and carbon is under closer control. Mr. Elliott suggests that a large share of these advantages is due to deoxidation rather than desulphurization. A sulphur content of 0.05 or even 0.07 is in practice now handled so as to be harmless. In other words, one would be unable to fix positively any pronounced advantage in gray iron castings with 0.03 per cent sulphur, due to this low content exclusively. On the other hand, since sulphur has such a tendency to segregate, 0.15 per cent sulphur will harm cast iron much more than three times as much as will 0.05—more like three times three. So well known is this that high-sulphur iron in good service is occasion for remark. Extremely low sulphur, 0.02 per cent, on the other hand, would be chiefly valuable in the assurance that one is far below any danger from this metalloid. A more natural use for foundry duplexing is the production of say 0.06 sulphur castings from 0.15 mixes, a practice which is easily and demonstrably economical in these days of poor coke, costly freight and high sulphur scrap. Electric-refined iron is materially harder than cupola iron from which it is made, more especially when made into small castings. This is largely due to the fact that the manganese otherwise used in making sulphide now exists as carbide, which is a hardener. "This question of hardness is intermingled with the closely related subjects

of the increased attraction of high-manganese irons for carbon, and of the protective influence of high manganese against oxidation in the cupola."

CASTINGS FOR MACHINE-TOOL BUILDERS

Two interesting talks on making castings for machine-tool builders were given by L. M. Sherwin, of the Brown & Sharp Manufacturing Co., and A. N. Kelley, of the Modern Tool Co. Such castings are seldom produced in large quantity, and, like most others, are made by more or less unskilled men, yet they must be of very high grade, for they are bought by men who know good castings when they see them. A large proportion must be finished all over, so that the slightest porosity would be ruinous. Tables, columns and arms must not warp; must have a fine grain and take a high finish; must be hard to resist wear yet not so hard as to give difficulty in machining. Much of the molding—even to the core making—is done by machines. Green sand molds, properly made of carefully selected sand and faced with 7 to 1 sand and sea-coal mixture, have been very successful. When chills are necessary, they should be sectional, separated somewhat one from another—large chills warp badly and have a very short life. For green molds chill blocks should first be washed with linseed oil, sprinkled with silica sand, and then baked in a core oven. Cupola mixtures must be carefully maintained, and the melting so done as to produce hot clean iron. A siphon tap and mixing ladle are advantageous, but even then special attention must be given to skimming the pouring ladles carefully. Long, flat castings may be poured simultaneously from both ends through horn gates—such rapid filling insures hot iron in all parts of the mold. Another method is to incline the mold so that the flat surface is tilted at about 6 deg. (gated at the lower end). This prevents the iron thinning out and chilling in layers.

HEAT TREATMENT OF STEEL CASTINGS

A meeting devoted to Steel Castings paid considerable attention to complex heat treatments to produce special qualities. Steel founders in general think of heat treatment as meaning annealing to break up ingot struc-

FIG. 1. TEST DATA SHOWING HEAT UNIFORMITY OF ELECTRIC FURNACE

ture. The possibilities of more complex treatments—normalization at various temperatures, drawing or tempering at various temperatures, and quenching at

FIG. 2. BATTERY OF THREE VERTICAL ELECTRIC HEAT-TREATING FURNACES FOR GUN FORGINGS

different speeds from different heats—are by no means realized as yet, and a great amount of educational work on fundamentals will be necessary to establish the heat treater in steel foundries. Such papers as that by Fred Grotts, of the Holt Manufacturing Co., will therefore do much to open the eyes of steel founders to the possibilities of their materials, and may also cause the forge-shop men to look to their laurels.

C. H. Gale, of the Pressed Steel Car Co., produced some interesting figures on the absorption of carbon and sulphur when annealing 0.26 carbon steel castings with pulverized coal (2½ per cent S). While no details of the furnace, method of burning, or analysis of furnace atmosphere were shown, the author gives chemical tests tabulated in Tables I and II.

TABLE I. CARBON AND SULPHUR ON REPEATED ANNEALING

	Original Analysis	First Anneal	Second Anneal	Third Anneal	Gals.
Carbon	0.265	0.291	0.317	0.326	0.061
Sulphur	0.042	0.052	0.055	0.056	0.014

TABLE II. CARBON AND SULPHUR IN SURFACE LAYERS AFTER FIRST ANNEAL

	Original	1 In Deep	1 In Deep	1 In Deep	1 In Deep
Carbon	0.286	0.298	0.293	0.288	0.285
Sulphur	0.046	0.055	0.052	0.049	0.047

These results were sufficient to convince the author that increased tensile strength but decreased ductility and transverse bending were due to the change in chemical composition.

Some data on the operating costs and the temperature distribution in vertical furnaces heated by electrical resistors of looped metallic ribbon were given by E. F. Collins, of the General Electric Co. Fig. 1 is a sketch of a moderate sized automatic furnace of this type, and

TABLE III

Time	1	Thermocouples—Temp. Deg. C.	3	4	5
11:30	25	25	25	25	25
3:30	527	537	532	530	545
7:30	670	679	671	666	669
11:30	777	783	776	766	780
3:30	858	864	857	849	864
7:30	860	865	862	862	863
11:30	928	934	930	930	928
3:30	933	932	927	925	927
4:30	950	950	952	952	955

a temperature survey given in Table III shows a remarkable uniformity. Fig. 2 gives a view, with covers rolled back, of a battery of three such furnaces

6 ft. diameter by 25 ft. deep. Average furnace charge was eleven tons, which was heated uniformly to 1,450 deg. F. with the expenditure of 178 kw.-hr. per ton. After quenching, the forgings were drawn at 1,150 deg. F. in similar furnaces with the expenditure of 85 kw.-hr. per ton. Both heatings together cost \$2.23 for power (rate = \$0.0085 per kw.-hr.). Total cost of heat treatment on 24-hr. operating basis for the month before the armistice totaled \$2.76 per ton.

Institute of Metals Sessions

A STUDY of Brass Foundry Fluxes was presented by A. C. W. Hill, T. P. Thomas and W. B. Vies of the Westinghouse Company. Such fluxes are added to molten metals preparatory to casting, in order to remove small amounts of impurities introduced by the melting process. Popular materials are NH_4Cl , ZnCl_2 , NaCl , and borax. Chemically the chloride flux is supposed to effect double decomposition with dissolved or admixed oxide, or to be reduced by the metal itself. However, the authors have been able to cause good fluxing of finely divided aluminum particles by adding aluminum chloride, which is the reaction product of any possible chemical interchange with contained chlorides, and which is itself without any chemical action on the metal or its oxide. Careful tests on molten aluminum have given the same chemical analyses both before and after fluxing, yet the physical effect is marked and extremely rapid. The authors conclude, therefore, that the action is largely physical or mechanical, and suggest that perhaps rapid evaporation of the flux at the points of contact with the surface film may burst this film, allowing the molten particles to unite. Gillett has caused complete coalescence of hot particles by pressure and heat, using no flux whatever. A secondary action of a flux may also be the partial or complete solution of the surface films in the flux before its volatilization.

Fluid covers are supposed to prevent gas absorption—borax, in addition, will dissolve metallic oxides which reach the metal: flux interface. However, most of the common coverings are permeable to hydrogen, which indeed easily passes through a hot crucible wall. In this connection the same authors have studied the solubility of hydrogen in molten copper and brass by bubbling the gas through a silica tube for twenty to thirty minutes, allowing the molten metal to rest at constant temperature for ten minutes, then teeming it into a closed crucible and aspirating the gas evolved upon solidification. The amount dissolved in copper varies with the temperature, as follows:

Saturation Temp., Deg. C.	Hydrogen Evolved on Solidification Mg. per 100 g. metal
1,100	0.60
1,150	0.725
1,200	0.85

Similar tests were made on brasses; plotting against composition, the curve has a minimum at 71 per cent copper and a maximum at 61 per cent copper, thence running off to zero at 36 per cent copper. Preliminary experiments on CO and CO_2 show about the same characteristics as were found for hydrogen.

Since soundness of castings, especially large castings, is dependent upon gas evolution during solidification, it is essential to regulate the composition of the flame, even in covered crucible melting. Phosphor-copper does not remove hydrogen—copper oxide will, but the melt in that case must be further doctored for its oxygen content.

TESTING OF SANDS, CORES AND BINDERS

Recognizing that the ideal test of a new product is its actual use in comparison with a satisfactory article regarded as a standard of excellence, it is also true that the personal equation and a multitude of difficultly controlled variables make it necessary for such a service test to continue for some little time. Preliminary laboratory examinations are then of value even if only to indicate whether a proposed new product has any reasonable chance of succeeding in the plant. F. L. Wolf and A. A. Grubb, of the Ohio Brass Co., have therefore devised certain tests for foundry sands, cores and binders. An ideal core, for instance, should be fairly strong while green, very strong when baked, easily destructible after use, smooth surfaced, permeable, of low gas content, work easily and pleasantly in coremakers' hands. Low-power microscopic examination will give some information to the skilled observer. Shape of grain is not so distinctive as lack of mica, feldspar, calcite, clay and loam. Grains covered with dark films may be expected to absorb an unduly large amount of binder. Screen analysis, up to 200-mesh, will also give considerable information. However, the shape of the grain will have great influence on the relative permeability of sands of similar fineness, even though the percentage of voids is little different. Permeability may be measured by placing a measured amount of sand in a 6-in. U tube. This tube is connected to a 400-c.c. water column aspirator, and the time necessary for this water column to draw a measured quantity of air through the sand gives a figure inversely proportional to the permeability. Cores may also be tested by the same aspirator. A $\frac{1}{2}$ x 3-in. core is dipped in melted paraffine, the ends cleaned and then closely fitted into a metal tube connected to the water column. Time necessary to draw a measured amount of air lengthwise through this core is taken as an inverse measure of permeability. Gas content is measured by noting the loss in weight after burning a baked core in an electric furnace at 1,400 deg. C. Linseed oil as binder ordinarily gives less than 1 per cent gas content, and the burned core will usually crumble easily between the fingers. Strength of green cores can be taken by observing its self-supported length as a cantilever. Baked cores are tested in the standard cement testing machine for tensile strength.

RECLAIMING METAL FROM SLAG AND SWEEPINGS

F. L. Wolf and G. E. Alderson described the methods used by the Ohio Brass Co. for reclaiming metals from slag and sweepings, presenting figures derived from a study of a week's operations. A quantity amounting to 8,666 lb. of "slag" (skimmings) from seventy-one tons metal melted was crushed through a 4-mesh riddle, the undersize, analyzing about 20 per cent Cu, sent to a feed bin, and the oversize, amounting to 1,967 lb., returned to stock, it being clean metal. Credited at 17c. per lb., it represented a value of \$335, recovered at a cost of \$15.50.

Clean-up from thirty-five molding floors amounted in a week to 21,600 lb. of sweepings, consisting of heavy metallics, spillings, cores and sand. Undersize of 40-mesh screen amounted to 14,050 lb., analyzing less than 1 per cent copper, and was wasted. Through 3-mesh on 40-mesh amounted to 3,770 lb., analyzing 25 per cent copper, and was sent to the feed bin for further concentrating. Metallics amounting to 1,296 lb. were picked from the oversize, which at 17c. per lb. was alone worth \$220; recovery cost \$41.

Refractories for Electric Furnaces

AN INTERESTING symposium on refractories for electric furnaces was held by the Electric Furnace Association in Columbus, Ohio, Wednesday, Oct. 6. Requirements for high-temperature service were first listed, and then stock was taken of our present raw materials and finished products, contrasting their good points against their shortcomings, with definite recommendations for usage apt to develop the best service. Finally an account was given of some investigative work under way from which might be expected the development of a more useful refractory for extremely high temperatures.

SUPERLATIVE REQUIREMENTS FOR ELECTRIC-FURNACE REFRACTORIES

A contribution from the Foote Mineral Co. outlined the superlative requirements for electric-furnace refractories, noting first that refining furnaces, handling metal and corrosive slag at temperatures limited only by the melting point of the furnace itself, have about reached the limit of their possible development. A new, cheap, dependable refractory with a melting point higher than 1,750 deg. C. is now required, a substance which is highly resistant to sudden temperature variation so as to permit intermittent operation, which has been calcined at electric-furnace temperature and which therefore may possess reasonable constancy of volume. It must resist the scour of slag—or if a roof brick, must withstand the action of fume, hot gases and splatters of liquid. It must be a poor conductor of electricity, else leakage of current may be serious. Lastly, it must have sufficient strength at high temperatures so that arches and side walls may hold up.

Manifestly none of our present refractories possesses all these properties at once, as pointed out by several speakers, notably R. M. Howe of the Mellon Institute, H. F. Staley of the Bureau of Standards and A. F. Greaves-Walker, of the American Refractories Co. Fireclay brick are in widest use in the general metallurgical industry, and many electric-furnace sidewalls are built up with them, but unless the walls are very thin and radiate heat very rapidly, or are water cooled, the inner surfaces melt down quickly, or soften and absorb quantities of slag and metal from the bath. Silica brick, particularly from Pennsylvania and Wisconsin materials, have given best service in roof arches. Silica brick melt at about the same temperature as fireclay, but retain their shape and much of their strength to a high temperature. On the other hand, they suffer wide variation in size if not properly burned, and in any case must be heated or cooled at a low rate. Calcined dolomite, although cheap, air slakes readily, consequently its use is confined to making tamped furnace bottoms and for patching.

Magnesite brick appears to be about the best and most usable of our refractories. Mr. Walker was loud in its praises, and was sure that when the Austrian magnesite re-entered the American market in quantity, much of the present complaint against unsuitable furnace linings would vanish. While MgO is reduced by carbon at 1,800 deg. C., at lower temperatures it withstands corrosion from most melts, fireclay and water vapor being its two greatest enemies. For best results its lime content should be low, and its tendency to spall may be successfully combated by keeping moisture away and preventing strong temperature changes. High lime magnesite or magnesite with 10 to 12 per

cent slag admixture is often used for basic furnace bottoms. Mr. McCoy reported a microscopic examination of such a bottom after 200 heats. While the material tamped in contained 16 per cent CaO originally, it now analyzed but 4 per cent, the remainder having been fluxed or worked out. Structurally it was a complex consisting of periclase crystals (MgO) cemented by monticellite, the calcium-magnesium ortho-silicate. Rockwell called attention to the successful use of steel-clad magnesite blocks for bottoms, and particularly in panels built in sidewalls at hot spots near electrodes. A soft-steel box of brick size, with one end missing, is rammed hard with ground dead-burned magnesite. These are not burned, but after drying are laid as headers; upon heating, the iron case melts and a "jointless" surface results which by virtue of its manufacture is more porous than the pressed burned brick, and will stand more rapid temperature changes with less danger of spalling. An instance was cited of a furnace manufacturing chromium-vanadium steel. Whereas thirty heats were the best record on a brick lining, 111 heats were procured from the tamped blocks.

Chromite brick have also been of unsatisfactory quality for many years. Local ores contain only 30 to 40 per cent Cr₂O₃, and brick made of them fail at low temperature. Meantime open-hearth furnacemen have discovered that a layer of chromite is not necessary to separate magnesite from silica brick, consequently their greatest use has been lost. The brick themselves are difficult to make on account of lack of a good bonding substance, and they have a high thermal conductivity. On account of their resistance to either acid or basic baths, however, good chromite brick might be utilized for several courses in sidewalls, near the slag line.

Bauxite is favored as a lining for the hot zones of cement kilns. Other metallurgical uses have not been so successful. As a brick it is difficult to make because of the lack of a desirable binder; it shrinks continuously under heating unless the raw material has been calcined and the brick burned at the most extreme temperatures. After such treatment successful basic bottoms of bauxite have been reported analyzing as high as 15 per cent SiO₂, although 5 per cent would have been a much safer figure. Even fused alumina brick cannot be used in furnace roofs, since they react readily with lime vapors.

This list about exhausts the common refractories now on the market, firebrick which have been in use long enough and in such quantity as to be out of the experimental stage. Alundum and carborundum have been under examination as furnace refractories for some time. Despite their cost, their use may easily prove economical; particularly has this been demonstrated when used as door jambs. Carbon, either amorphous or graphitized, also has special applications in furnace bottoms.

CARBORUNDUM AS A REFRACTORY

Carborundum as a refractory was discussed at length by Dr. M. L. Hartman, in two papers—one at this meeting and the other read before the Foundrymen's convention. Four types are now on the market: (a) Recrystallized carborundum, which are shapes passed through the electric furnace the second time, the bond consisting of intergrown crystals; (b) three kinds of bonded carborundum, shapes composed of small crystals bonded with certain refractory mixtures; (c) various cements for molding shapes directly in furnaces and for

patching, consisting of carborundum with different bonding materials; and (d) firesand, a furnace byproduct consisting principally of silicon carbide and partially reduced oxycarbides, suitable for rammed-up linings.

From these products a wide variation in refractories can be obtained. In general, however, while carborundum has a very high decomposition temperature, it begins to dissociate appreciably under oxidizing conditions at about 1,500 deg. C., and under reducing conditions at 1,700 deg. C. Lead oxide reacts with silicon carbide very rapidly. Iron, steels and their ordinary slags also decompose carborundum. It has no softening or transition temperature short of decomposition; its thermal conductivity is high, its coefficient of expansion is low, it resists non-ferrous metals except lead, and it is extremely hard and durable. A bonded variety is made with good electric resistivity at high temperatures.

Detailed applications are cited. The Baily furnace may have the trough containing the carbon resistor molded of firesand, which has a high electrical resistance, is refractory, and is unaffected by carbon and CO. In the General Electric contact arc furnace, the walls may be of carborundum shapes, highly refractory and with a low coefficient of expansion, thus avoiding metal leakage. Arc furnaces in ferrous service may have roofs of carborundum held very close to the bath, which is desirable, but only if the electrodes enter through insulating sleeves. In non-ferrous practice, the rotative furnaces are popular, heating the metal largely from the lining, which of course must withstand the mechanical wear. To reduce the extreme first cost, an effort is being made to develop a composite lining, consisting of a thin inner coat of carborundum, a stout backing of cheaper refractory, and an outer sheath of insulator. As a matter of fact, the discovery of a really good insulator which stands up and still insulates when heated to a high temperature would cause a revolution in the use of refractories. At present low-melting brick are purposely cooled, wasting enormous quantities of heat in order to maintain the furnace structure. With an efficient insulator a thin lining of some really heat-resistant material could be used, whose present use to build walls is prevented on account of its high cost.

NEW AND BETTER REFRACTORIES

After this discussion of the natural and artificial refractories which are now available in quantity, Mr. Stull, of the Columbus station, Bureau of Mines, together with H. F. Staley, of the Bureau of Standards, pointed out the direction from which new and better refractories might be expected. A study of the $\text{SiO}_2\text{-Al}_2\text{O}_3$ equilibrium diagram revealed one compound, sillimanite, with a melting temperature about 1,820 deg. C. This mineral is not available in commercial amounts, but a synthetic product of this composition has been made and used. For instance, Mr. Berry noted that aluminous brick containing high silica had proved very good for rocking brass furnaces. Commercially it is manufactured by mixing proper proportions of fireclay and bauxite, grinding, and calcining at 2,700 to 2,800 deg. F. in a fuel-fired kiln. The resulting clinker is then crushed, bonded with a little of the original slurry, slop molded, repressed, dried, and burned at the maximum temperature possible in the ordinary kiln (2,800 deg. F.—far below the melting point of sillimanite).

A similar compound, spinel ($\text{MgO}\cdot\text{Al}_2\text{O}_3$), occurs in that system, melting at about 2,130 deg. C. Like sillimanite, it should remain rigid nearly up to its melting point—melting at a fixed temperature, and not, like a fireclay, through a temperature range. Spinel brick have double the life of magnesite when used as charging doorsills, and should be no more expensive in first cost.

Zirkite brick, made from calcined zirconium carbonate, are also in experimental use. Unfortunately the commercial carbonate usually is high in silica. Zirconia also reacts easily, forming carbides at high temperatures. The last fault does not apply to micron brick, made of the mineral $\text{ZrO}_2\cdot\text{SiO}_2$. This compound melts at about 2,560 deg. C., but it is very difficult to make brick with a satisfactory bond. Aluminous binders especially must be avoided. Ground ore is the best agent, but this requires a burning temperature far above the possibilities of any but an electric furnace. Even here the difficulties in getting a uniform high temperature throughout a large volume are obvious and almost insurmountable.

Fused zircon, according to Staley, has permanent volume. It is an acid refractory, being attacked by basic slags and hydrofluoric acid, but not by molten silica. It has a low coefficient of thermal expansion, but at the same time a low thermal conductivity; consequently it is liable to check badly on sudden temperature changes. It has a high electrical resistance. All in all, and especially in view of the occurrence of the mineral zircon in quantity, this refractory presents the best chances for immediate improvement for acid linings.

A Rapid Qualitative Method for Nickel in Steel

BY MELVIN B. DANHEISER*

The method here described was developed as a reliable method for separating nickel steel from other steel without cutting samples for a regular chemical test. In many cases this test can be used on finished steel parts without destroying the piece. The complete test can be made in three to five minutes.

A few filings (about the amount that can be heaped on the head of a pin) are placed upon a watch glass $1\frac{1}{2}$ in. in diameter. A drop of nitric acid sp.gr. 1.42 is added from the end of a glass rod. If action does not start immediately, warm slightly. Allow to effervesce for one-half minute. Add a drop at a time of the ammonia-dimethylglyoxime reagent until action ceases and the solution becomes pink. Allow to stand one minute, place under microscope using a 16 mm. objective and examine for crystals of nickel dimethylglyoxime, which occur as pink needles but when massed have the appearance of a pink pulp.

With a steel containing no nickel a pink or red solution is formed which turns brown on standing. No crystals occur until the solution has evaporated almost to dryness and then they are brown and distinctly different from the nickel dimethylglyoxime crystals.

In order to become familiar with this test a small crystal of a nickel salt is put through the same procedure as the steel and the crystals formed compared with the steel under test.

The ammonia-dimethylglyoxime reagent is made as follows: 5 g. of citric acid is dissolved in 90 c.c. of 1:1 ammonium hydroxide sp.gr. 0.90 and 10 c.c. of a 1 per cent solution of dimethylglyoxime in alcohol added.

Varnish Fume Recovery

New Methods of Recovering Fume From Three Stages of Varnish Manufacture—Description of Plant at the Arco Co.—Other Installations—Experimental and Operating Data—Chemistry of Gum Distillation—Possible Future for Recovery Products

By CHESTER H. JONES

AS SO often occurs in other industries, the necessity for the protection of the workmen and the neighborhood from objectionable fumes developed in the manufacture of varnish has resulted in an economy for this industry which will go far toward putting it on a scientific basis. It has only been a question of months since the making of varnish in all factories was simply a cooking operation similar to a high-class bakery or ordinary vegetable cannery. The gums were dumped into open copper or iron kettles in proportions dictated by secret "deathbed formulas" and cooked over a coke fire to a point where the "expert" varnish maker determined the batch to be finished. No chemical control was used, and as there was little to keep secret, deep secrecy was therefore maintained.

The fumes from the kettles, mingled with those from the fire, sometimes passed up the stacks—especially when the wind was right—as the builder hoped they would, and were dissipated in the form of a disagreeable "foreign" odor over the surrounding countryside. Fig. 1 shows an installation of this type so common today.

At the conclusion of the cooking the kettles were drawn to the cooling shed, thence to the reducer room, where certain thinners such as light oils and turpentine were poured into the warm mass. This was an occasion of more fumes, obnoxious to the workmen and incidentally a direct loss of the volatile thinner liquids to the manufacturer.

The foregoing paragraphs should be written in the present tense to be strictly accurate, for the description covers the operations in most plants today. The old-time stack process will, however, soon be superseded in progressive plants.

At any rate, the method continued in general use until the officials of a hospital in Providence, R. I., began to complain of the fumes from the plant of the U. S. Gutta Percha Paint Co., and after considerable study on the part of the technical staff the first modern recovery plant was installed there in January, 1918. Since that time the engineers, Perry & Webster, Inc., have issued licenses to sixteen different varnish makers either for the new type stackless plant or for installations in old-type stack plants, for the purpose of recovering values from the fumes developed in both the cooking and thinning operations.

Like most chemical engineering work, the new method comprises the simple application of well-known mechanical principles to existing chemical processes. One of the more recent installations is just going into operation at the plant of the Arco Co., Cleveland, Ohio, and is therefore most suitable for a detailed description of the method.

THE ARCO CO.

This organization is an excellent example of the progressive type of paint and varnish manufacturer, as

evidenced by the employment over a number of years of a physical, chemical and japan testing laboratory in control of the plant operations and in research for better methods. Fig. 3 shows a section of the chemical laboratory. All raw materials are analyzed and samples from each batch of finished varnish are held for two years against complaint from the consumer. The laboratory work is divided into four departments—namely, house paint and enamels, machinery finishes, automobile color and varnish and finishes, and japanning and baking enamels.

Tests are made both at the finish of the batch and after thirty days' standing. If trouble is encountered, the goods are returned, but if laboratory tests prove satisfactory, trouble men are sent out to help the consumer.

Naturally a company pursuing such policies would be among the first to adopt the new recovery methods.

VARNISH RECOVERY PLANT

Fig. 2 is the building at the Arco plant housing the new sixteen-fire, two-story stackless varnish process. It is designed for future extension to forty-eight-fire capacity. Note the basement entrance in the foreground arranged for trackage to remove ashes. The ashpits are all below the operating floor and are so arranged that gas or oil firing may be substituted for the coke grates at any future time. The large stack has no connection with the process. The two steel stacks at the end of the building lead from the exhausters which create the positive draft on the coke fire. The door on the side of the building at the extreme left opens into the elevator shaft through which raw materials are lifted to the second floor, daily storage, shown in Fig. 4.

Here the solid materials are stacked in concrete compartments, while the various oils are pumped to tanks directly above. In charging, the gums are shoveled into the hoppers appearing in the center on the floor and the oils are emptied through a battery of pipes terminating near a Kron platform scale in the operating room.

Fig. 5 shows the melting or operating floor, with eight fires on each side. The pair of overhead rails carry a traveling weighing hopper which is filled with the gums through the spouts leading from the hoppers above described and empties directly into the cooking kettles conveyed on trucks beneath. When a kettle is charged with gums it is wheeled onto the platform scale to receive the necessary charge of oils. The traveling hopper may also be moved into the cooling and thinner rooms on the overhead rails.

The two Buffalo Forge Co. planing mill exhausters for the fire combustion smoke appear on the balcony at the extreme end of the room. (Exhauster stacks shown outside in Fig. 3.) The positive suction over each fire insures sufficient draft to secure nearly perfect

combustion with a scarcely noticeable smoke issuing from the stacks. These exhausters have no connection with the fume-recovery system.

COOKING OPERATION

The charged kettle is placed over the fire and fume exhaust cover is lowered as shown in Fig. 5. These covers are shown raised in the left hand bank. The lids are attached to a collapsible swinging pipe which is easily manipulated by hand. Tycos thermometers attached to long pipes are thrust through the kettle door into the mass as shown in the hand of the operator to the left in Fig. 5.

The cooking time required about an hour and a half under the old system, but thirty minutes is sufficient with the new arrangement. The temperature varies with the formula of the mix, but the maximum requirement is about 750 deg. F. (399 deg. C.). The lid and exhaust system minimizes the possibility of a batch flashing or burning as under the old method. Screens are inserted in the flues to localize spontaneous combustion. Before passing on to the fume recovery system compare the operating floor with the old method shown in Fig. 1 as carried on in the same factory.

COOLING THE BATCH

Because of the high temperature of the melt when removed from the fire it is not possible to add the volatile thinners until the batch has been considerably cooled. The kettles are therefore drawn to the cooling room on the same floor and placed beneath lids with flues connecting to the same fume exhaust recovery system as operates in the cooking process. A corner of the cooling room appears in Fig. 6. Here the electric switches are also located and from this point the operator may control any motor in the plant, including those in the third floor penthouse.

VARNISH FUME RECOVERY

The fumes from the two sources mentioned above are drawn through a water-scrubbing tank located in the penthouse where the heavy particles settle out and the remainder passes through the turbine, Spencer Turbine Cleaner Co., to a similar tank filled with lime water, where the finer particles are precipitated. The apparatus for one bank of eight fires is shown in the foreground of Fig. 7.

There are three points of recovery from the fume system. First, the product which condenses on the inner surfaces of the piping ahead of the water tank and which is piped back to the kettles from convenient points in the line; second, the condensate caught in the water-scrubbing tank which settles to the bottom and is drawn off to be eventually returned to the kettles; and third, the product of the lime water-scrubbing tank, a sort of lime soap or emulsion, which is boiled to remove the excess lime water and neutralized with acid before returning to the kettles.

The amount of fume which is finally released to the atmosphere is so small as to be scarcely discernible to the eye and has only a slight soapy odor. The vacuum maintained on the kettles is just sufficient to carry off the fume and give a minimum amount of work to the scrubbing tanks.

The thinner recovery system operates entirely separate from the combustion or fume recovery system. When the kettles are sufficiently cooled but still warm they are wheeled to the thinner room, a section of which appears

in Fig. 8, and placed beneath the movable lids. The oils or thinners are added to produce a varnish of the desired consistency. These thinners are so volatile it is necessary to maintain a suction on the line during the operation to carry the fumes into the flues, where they are condensed in the cleverly constructed piping system, the condensate flowing back to the kettles. A Buffalo Forge Co. planing mill exhauster is installed on the roof to produce the required vacuum and the air, containing less than 2 per cent of the total volatiles used, is carried directly to the atmosphere. It is reported by one manufacturer that whereas 8 per cent of the total thinners employed were previously lost 6 per cent of the total is now recovered, giving a net loss of only 2 per cent.

CLARIFYING FOR THE MARKET

While this completes the description of the new process at the Arco plant, it seems pertinent to mention the method of finishing the product for the market. The varnish is pumped from the kettles in the thinner room to large settling tanks, thence through a centrifugal separator of the DeLaval type to the final storage. The centrifugal method of clarifying as shown in Fig 9 is thought much superior to other means involving filtration. Fig. 10 shows a battery of tanks containing separate manufacturing lots ready for the market.

OTHER INSTALLATIONS

Before taking up the economies effected through this system it may be helpful to show two other installations. The Patterson-Sargent Co., of Long Island City, N. Y., installed a six-fire unit several months ago. It has operated successfully from the start. Fig. 11 shows the building, with penthouse on top and condenser pipes on the outside. The large stack has no connection with the varnish recovery. The elbow pipe on top of the penthouse carries the final exhaust from the varnish kettles and the square stack emits the combustion gases. Room has been provided for installing an additional unit of six fires. Connersville blowers were used on the fume system.

Fig. 12 shows the fires in the melting room, and the cooling apparatus is seen through the doorway on the left. Fig. 13 also shows the cooling room and storage with provision for additional units. The building was planned to house an old-type stack plant, but during the process of erection was changed to accommodate the new fume recovery system. This accounts for the unnecessary amount of overhead space in the cooling room.

Fig. 14 is one of the fires in the original installation at Providence, R. I., where a stack plant was changed to accommodate the stackless system. Roots blowers were installed on the exhaust line.

One of the latest design two-story plants just being erected in the West is shown in plan and section, Figs. 15 and 16. Out of sixteen plants only two have been installed for the primary purpose of eradicating the nuisance to the neighborhood arising from the escaping fume; the benefits of recovery of fume value, fire prevention, increased efficiency and lessened cost of operation were inducements in the other instances.

COOKING LOSSES IN STACK PLANTS

While operating losses are somewhat hard to determine accurately on a weight basis due to the fact that the blend or mix consists of several gums of varying specific gravities and values and to the fact that there are gains in weight through chemical reactions such as

Fig. 1. Common type of varnish-making installation.
 Fig. 3. Section of chemical laboratory.
 Fig. 5. Melting or operating floor.
 Fig. 7. Varnish fume-recovery apparatus.

Fig. 2. Arco Company plant.
 Fig. 4. Storage room.
 Fig. 6. Cooling room.
 Fig. 8. Thinner recovery apparatus.

Fig. 9. Centrifugal clarifiers.
Fig. 12. Melting room.

Fig. 10. Storage tanks for finished products.
Fig. 13. Cooling room and storage.

oxidation, considerable data have been prepared by several operators. The following from Circular 96 issued by the educational bureau, scientific section of the Paint Manufacturers' Association of the U. S., in co-operation with the National Varnish Manufacturers' Association,

shows that the over-all loss runs from 12 to 20 per cent and the actual gum loss may run from 30 to 42 per cent of the amount used in the varnish.

The figures are all on losses shown by varnish bases previous to reducing by turpentine or other thinners.

GUM LOSS IN KETTLE

	Overall loss by Weight, per Cent	Loss of gum Used by Weight, per Cent
Long Oil Kauri Varnish	12.4	30
Short Oil Kauri Varnish	20.0	34
Long Oil Manila Varnish	16.0	40
Short Oil Manila Varnish	20.0	42

PROPORTION BY WEIGHT OF OIL AND OF GUM IN FUME

	Oil, per Cent	Gum, per Cent
Long Oil Kauri Varnish	33.1	66.1
Short Oil Kauri Varnish	11.5	88.5
Long Oil Manila Varnish	27.3	72.7
Short Oil Manila Varnish	12.5	87.5

This latter table shows that the gum loss is greater in weight. If the cash value is considered the proportionate loss is even greater, as follows:

FUME LOSS PROPORTIONS IN MONEY VALUE

	Oil, per Cent	Gum, per Cent
Long Oil Kauri Varnish	15	85
Short Oil Kauri Varnish	5.4	94.6
Long Oil Manila Varnish	24.7	75.3
Short Oil Manila Varnish	11.0	89.0

FIG. 11. THE PATTERSON-SARGENT PLANT

FIG. 14. ONE OF THE FIRES IN THE ORIGINAL INSTALLATION AT PROVIDENCE, R. I.

Further tests made on losses in cooking oils alone, given in Bulletin 95 issued by the Educational Committee are also of interest.

	Sp. Gr.	Loss Percentage Weight	Loss Percentage Volume
Raw Linseed Oil:			
500 deg. F. (260 deg. C.), for 4 hr.	0.9477	2.90	4.46
550 deg. F. (290 deg. C.), for 4 hr.	0.9690	8.60	12.05
Varnish Makers' Linseed Oil:			
500 deg. F. (260 deg. C.), for 4 hr.	0.9482	2.20	3.88
550 deg. F. (290 deg. C.), for 4 hr.	0.9666	5.40	8.79
Fish Oil (Menhaden):

Sunflower Seed Oil:			
500 deg. F. (260 deg. C.), for 4 hr.	0.9145	4.04	5.12
550 deg. F. (290 deg. C.), for 4 hr.	0.9430	9.33	11.16

In his bulletin "Fume Control in the Varnish Industry," Henry A. Gardner says: "The equivalent of a varnish kettle running continuously on one of these type varnishes would thus indicate a yearly fume loss on gum and oil equivalent in money to the cost of the products lost. It should, however, be pointed out that even entire recovery of fumes would not necessarily mean recovery of the original value of the products from which they were derived. This is due to the fact that oil and gum fumes recovered as condensates by any system are of different composition than the materials of their origin and of much less money value. Nevertheless, the data show the importance of fume recovery; and it is quite possible that certain products might be fractionated from condensed gum fumes that would have an even greater money value than the original gums."

Those who have witnessed the new plants in operation are strongly impressed with the facts that a negligible amount of fume is released to the atmosphere, that a large amount of material is directly recovered as primary condensate and that there is unlimited scope for development by research of the products taken in the water and alkali scrubbers. Manufacturers using the new plant are enthusiastic over this last point.

Considerable importance is given in Mr. Gardner's

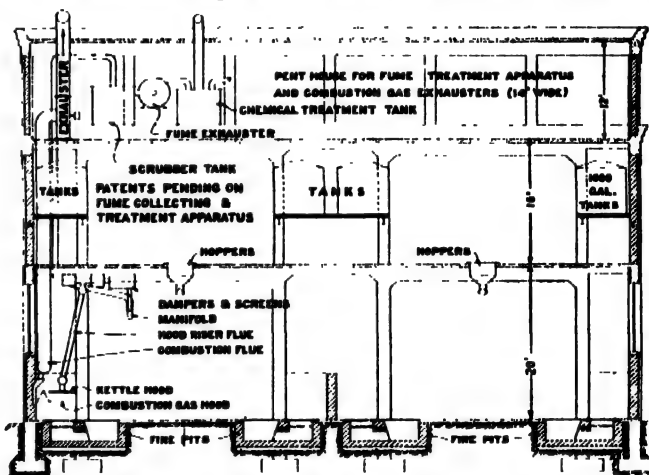

FIG. 16. CROSS-SECTION 2-STORY, 24-FIRE, STACKLESS VARNISH PLANT

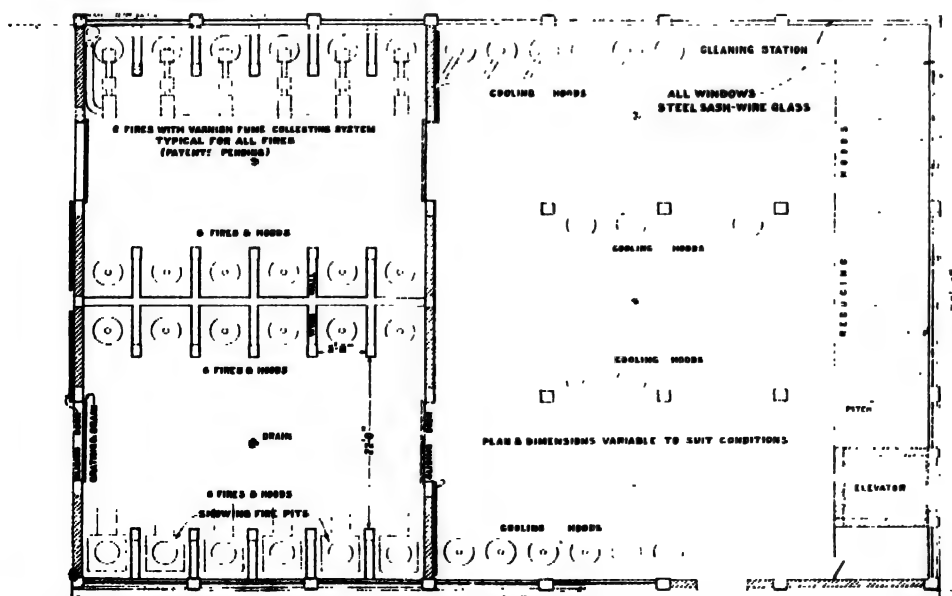

FIG. 15. FIRST FLOOR PLAN 2-STORY, 24-FIRE, STACKLESS VARNISH PLANT

bulletin to the work done by Smith and dePierres as presented before the Eighth International Congress of Applied Chemistry as to autoclave determinations of varnish materials.

RECENT DATA FROM ACTUAL PLANT OPERATION

The following fume loss data and calculations taken from a manufacturer's factory records on four typical high-grade batches under good practice with kettles covered while melting the gum and open during the cook-out and finishing, while unconfirmed by the writer, may be considered authentic. It is necessary only to figure the materials at present market conditions to see the large saving effected through fume recovery.

SHORT OIL MANILA VARNISH

Type, 10 gal. oil to 100 lb. gum	
Actual formula:	
Kettle Charge:	lb.
Hard white manila.	190 00
W.W.	10 00
Drier salts.	6 00
Treated oil (20 gal.).	155 00
Total kettle charge	361 00
Thinner turps (5 gal.)	35 00
Texaco (55 gal.)	357 50
Total formula	753 50
Oil loss prior treatment	12 00
Total materials used	765 50
Total yield of varnish	636 40
Loss, 20 per cent.	129 10
Distribution of Above Loss	
Oil loss:	lb.
On previous oil treatment (8 per cent of bulk)	12 00
Drier loss (figured at 50 per cent)	
Including loss of drier in oil treatment	6 00
Thinner losses:	
Turps and Texaco 6.85 per cent of amount used.	27 00
Total	45 00
Gum losses (by difference):	
42 per cent of original weight of gum used	84 10

LONG OIL MANILA VARNISH

Type, 25 gal. oil to 100 lb. gum	
Actual formula:	
Kettle charge:	lb.
Hard white manila.	200 00
Treated oil (50 gal.)	387 50
Total kettle charge	587 50
Thinners:	
Turps (5 gal.)	35 00
Texaco (55 gal.)	357 50
Total thinner used	392 50
Total formula	980 00
Oil loss on prior treatment	30 00
Total materials used	1,010 00
Total yield of varnish	870 00
Loss, 16 per cent	140 00
Distribution of Above Loss	
Oil loss:	lb.
On previous oil treatment (8 per cent of bulk)	30 00
Drier loss (at 50 per cent):	
Including loss of drier in oil treatment	3 00
Thinner losses:	
Turps and Texaco at 7 per cent of amount used	27 50
	60 50
Gum losses (by difference):	
40 per cent of original weight of gum used	79 50

SHORT OIL KAURI VARNISH

Type, 8 gal. oil to 100 lb. gum	
Actual formula:	
Kettle charge:	lb.
Ex. No. 1 Kauri	200 00
Treated oil (16 gal.)	124 00
Drying salts	10 00
Total kettle charge	334 00
Thinners:	
Turps (50 gal.)	350 00
Total formula	684 00
Oil loss on prior treatment	8 85
Total materials used	692 85
Total yield of varnish:	
78 gal. at 7½ lb.	585 00
Loss, 20 per cent	107 85
Distribution of Above Loss	
Oil loss:	lb.
On previous oil treatment (8 per cent of bulk):	
Volume loss 1.18 gal. at 7.75 lb.	8 85
Drier loss (at 50 per cent):	
Including loss of drier in oil treatment	7 00
Thinner losses:	
Turps at 6.8 per cent of amount used	24 00
	39 85
Gum losses (by difference):	
34 per cent of original weight of gum used	68 00

LONG OIL KAURI VARNISH

Type, 25 gal. oil to 100 lb. gum	
Actual formula:	
Kettle charge:	lb.
XX Kauri	200 00
Oil not treated (50 gal.)	387 50
Drier salts	4 50
Total kettle charge	592 00
Thinners:	
Turps (50 gal.)	350 00
Total formula	942 00
Yield	825 00
Loss, 12.4 per cent	117 00
Distribution of Above Loss	
Oil loss (8 per cent of bulk)	30 00
Drier loss (at 50 per cent)	2 25
Thinner losses:	
Turps at 7 per cent of amount used	24 50
	56 75
Gum loss (by difference):	
30 per cent of original weight of gum purchased	60 00

The oil measured and weighed cold at the start 100 gal. and 750 lb. and at the finish 92.6 gal. and 717.65 lb., giving a volume loss of 8 per cent. Previously treated linseed oil was used in all cases excepting the Long Oil Kauri Varnish in the last batch, on which, being taken without previous treatment, all shrinkage occurred in the kettle. Where the oil had been previously treated the shrinkage on factory practice was 8 per cent by volume and the weight per gallon increased from 7½ lb. for the untreated to 7.75 per gal. for the treated oil.

Drier losses are calculated on basis of one-half of all drier salts dropped out or left in filters from batch and also from drier used in oil treatment.

CONCLUSION

The new stackless system then is the practical application of theories long extant. Its mechanical features are such as to secure the desired recovery without radical departure from habits of previous operations. A development at once extremely beneficial in its chemical accomplishments and conservative in its mechanical features should be especially valuable for installation in the plants of going concerns. As each new industry is added to the growing list of those which have entered upon the era where economies are effected through technological considerations, where progress is speeded up through scientific control and research, there comes an increased inspiration to technical men in every line carrying them forward toward the vision where science and craftsmanship merge into art.

In conclusion the author wishes to acknowledge the courteous co-operation of Perry & Webster, Inc., and officials of the Arco Co. and the Patterson-Sargent Co. in supplying information and opening their plants to inspection.

America's Tobacco Industry

In the production of tobacco, the United States leads all other nations, the annual quantity being estimated by the Department of Agriculture at 1,000,000,000 lb. British India is second with about 450,000,000 lb. Before the war, Russia was third with 177,000,000 lb., the Dutch East Indies fourth with 163,000,000 lb., and Austria-Hungary fifth with 158,000,000 lb.

Figures for the United States production in 1919 are given as 1,389,000,000 lb., which at the present time represents more than half of the world's production.

Likewise, the United States is the biggest exporter of tobacco, having sent abroad 765,000,000 lb. in 1919.

Metallography of Arc-Fused Steel*

Various Lines of Investigation Are Utilized to Support the Idea That Microscopic "Plates" Existing in Fusion Welds Are Due to Nitrogen; That the Plates Are Very Persistent, and Are Not Responsible for the Low Ductility of the Metallic Piece

By HENRY S. RAWDON, EDWARD C. GROESBECK AND LOUIS JORDAN†

AN ARTICLE entitled "The Physical Properties of Arc-Fused Steel," published in *CHEMICAL & METALLURGICAL ENGINEERING* for Oct. 6, 1920 (vol. 23, p. 675) described the methods used in building up blocks of arc-fused metal of size large enough to furnish a tension specimen. Fusion welds evidently are fundamentally different from other types of joints in that the metal at the weld is essentially a casting. A preliminary study of a considerable number of specimens welded under different conditions confirmed the impression that the arc-fusion weld has characteristics quite different from other fusion welds.

In the present study, of which both the former contribution and the present form a part, two types of electrodes, a "pure" iron called "A" and a mild steel called "B," were used, in the bare condition, and also after receiving a slight coating. With these were included a set of similar specimens prepared outside of the Bureau by expert welding operators. During the fusion the composition of the metal of the two types of electrodes is changed considerably by the "burning-out" of the carbon and other elements, the two becoming very much alike in composition. A very considerable increase in the nitrogen content occurs at the same time, as shown by chemical analysis.

The mechanical properties of the arc-fused metal as measured by the tension test are essentially those of an inferior casting. The most striking feature is the low ductility of the metal. All of the specimens showed evidence of unsoundness in their structure, tiny inclosed cavities, oxide inclusions, lack of intimate union, etc. These features of unsoundness are, seemingly, a necessary consequence of the method of fusion as now practiced. They determine almost entirely the mechanical properties of the arc-fused metal. The observed elongation of the specimen under tension is

due to the combined action of the numerous unsound spots rather than to the ductility of the metal. That the metal is inherently ductile, however, will be shown by the changes in the microstructure produced by cold-bending. By taking extreme precautions during the fusion, a great deal of the unsoundness may be avoided and the mechanical properties of the metal be considerably improved. The specimens described, however, are more representative of actual present practice in welding.

GENERAL FEATURES OF MICROSTRUCTURE

For purposes of comparison the microstructure of the electrodes before fusion is shown in Figs. 1 and 2. The "A" electrodes have the appearance of steel of a very low carbon content; in some cases they were in

eter. Cold-drawn.

the cold-rolled state; all showed a considerable number of inclusions. The "B" electrodes have the structure of a mild steel and are much freer from inclusions than are those of the other type. It is undoubtedly true, however, that the condition of the arc-fused metal with respect to the number of inclusions is a result of the fusion rather than of the initial state of the metal.

It is to be expected that the microstructure of the material after fusion will be very considerably changed, since the metal is then essentially the same as a casting. It has some features, however, which are not to be found in steel as ordinarily cast. The general type of microstructure was found to vary in the different specimens and to range from a condition which will be designated as "columnar" (Fig. 3) to that of a uniform fine equi-axed crystalline arrangement (Fig. 4). This observation held true for both types of electrodes, whether bare or covered. In the examination of cross-sections of the blocks of arc-fused metal, it was noticed that the equi-axed type of structure is prevalent throughout the interior of the piece and the columnar is to be found generally nearer the surface—i.e., it

†Physicist, Physical Chemist and Associate Chemist, respectively, Bureau of Standards.

the metal deposited last. It may be inferred from this that the metal of the layers which were deposited during the early part of the preparation of the specimen is refined considerably by the successive heatings to which it is subjected as additional layers of metal are deposited. The general type of structure of the tension bars cut from the blocks of arc-fused metal will vary considerably according to the amount of refining which has taken place as well as the relative position of the tension specimen within the block. In addition it was noticed that the columnar and coarse equi-axed crystal-line condition appears to predominate with fusion at high-current densities.

MICROSCOPIC EVIDENCE OF UNSOUNDNESS

In all of the specimens of arc-fused metal examined microscopically there appear to be numerous tiny globules of oxide as shown in Figs. 3 to 12. A magnification of 500 diameters is usually necessary to show

needles were found to vary greatly in the different specimens. In general, they are most abundant in the columnar and in the coarse equi-axed crystals; the finer equi-axed crystals in some specimens were found to be quite free from them, although exceptions were found to this rule. In general, a needle lies entirely within the bounds of an individual crystal. Some instances were found, however, where a needle appeared to lie across the boundary and so lie within two adjacent crystals. Several instances of this tendency have been noted in the literature on this subject.¹ The needles have an appreciable width, and when the specimen is etched with 2 per cent alcoholic nitric acid they appear much the same as cementite—i.e., they remain uncolored, although they may appear to widen and darken if the etching is prolonged considerably. The apparent widening is evidently due to the attack of the adjacent ferrite along the boundary line between the two. The tendency of the lines to darken when etched with a hot

these inclusions. In general they appear to have no definite arrangement, but occur indiscriminately throughout the crystals of iron.

A type of unsoundness frequently found is that shown in Figs. 5, 6 and 7; this will be referred to as "metallic-globule inclusions." In general these globules possess a microstructure similar to that of the surrounding metal, but are enveloped by a film, presumably of oxide. It seems probable that they are small metallic particles which were formed as a sort of spray at the tip of the electrode and which were deposited on the solidified crust surrounding the pool of molten metal directly under the arc. These solidified particles apparently are not fused in with the metal which is subsequently deposited over them—i.e., during the formation of this same layer and before any brushing of the surface occurs. By taking extreme precautions during the fusion, a great deal of this unsoundness may be avoided and the mechanical properties of the metal may be considerably improved.

The most characteristic feature of the steel after fusion is the presence of numerous lines or needles within the crystals. The general appearance of this feature of the structure is shown in Figs. 8 to 11 inclusive. The number and the distribution of these

alkaline solution of sodium picrate, as reported by Comstock,² was confirmed. Fig. 10 illustrates the appearance when etched in this manner. The needles are sometimes found in a rectangular grouping—i.e., they form angles of 90 deg. with one another. In other cases they appear to be arranged along the octahedral planes of the crystal—i.e., at 60 deg. to one another. This is best seen in specimens which have been heated, as explained below.

In some of the specimens certain crystals showed groups of very fine short needles (Fig. 11). The needles comprising any one group or family are usually arranged parallel to one another, but the various groups are often arranged definitely with respect to one another in the same manner as described above. Similar needles have been reported in the literature by Miller.³

Fig. 11. Specimen of welded joint between slip-plate. Additional very small needles are noted. Etching: 2 per cent HNO₃ in alcohol.

An attempt was made by Dr. P. D. Merica to determine whether the so-called lines or needles were really of the shape of needles or of tiny plates or scales. An area was carefully located on a specimen prepared for microscopic examination, which was then ground down slightly and repolished several times. It was possible to measure the amount of metal removed during the slight grinding by observing the gradual disappearance of certain of the spherical oxide inclusions the diameter of which could be accurately measured. By slightly etching the specimen after polishing anew it was possible to follow the gradual disappearance of some of the most prominent needles and to measure the maximum "depth" of such needles. It was concluded from the series of examinations that the term "plate" is more correctly descriptive of this feature of the structure than "line" or "needle." The thickness of the plate—i.e., the width of the needle—varies from 0.0005 to 0.001 mm. and the width of the plate ("depth") may be as great as 0.005 mm. The persistence of the plates after a regrinding of the surface used for microscopical examination may be noted in some of the micrographs given by Miller.⁴ The authors are not aware, however, of any

other attempt to determine the shape of these plates by actual measurements of their dimensions.

PLATES PROBABLY DUE TO NITRIDES

The usual explanation of the nature of these plates is that they are due to the nitrogen which is taken up by the iron during its fusion. Other suggestions which have been offered previously attribute them to oxide of iron and to carbide. The suggestion concerning oxide may be dismissed with a few words. The plates are distinctly different from oxide in their form and their behavior upon heating. It is shown later that the tiny oxide globules coalesce into larger ones upon prolonged heating *in vacuo*; the plates also increase in size and become much more distinct (see Figs. 32, 34 and 36). In no case, however, was any intermediate stage between the globular form and the plate produced such as would be expected if both were of the same chemical nature.

Regarding the assumption that they are cementite plates, it may be said that the tendency during fusion is for the carbon to be "burned out," thus leaving an iron of low carbon content. In all the specimens, islands of pearlite (usually with cementite borders) are to be found and may easily be distinguished with certainty. The number of such islands in any specimen appears to be sufficient to account for the carbon content of the material as revealed by chemical analysis. In some cases the pearlite islands are associated with a certain type of "lines" or "needles" such as are shown in Fig. 12. These needles, however, appear distinctly different from those of the prevailing type and are usually easily distinguished from them.

The fact that the plates found in the arc-fused metal are identical in appearance and in behavior (e.g., etching) with those found in iron which has been nitrogenized is strong evidence that both are of the same nature. Fig. 13 shows the appearance of the plates produced in electrolytic iron by heating it for some time in pure ammonia gas. These plates behave in the same characteristic manner when etched with hot sodium picrate as do those occurring in arc-fused iron—i.e., they darken slightly and appear as finest rulings across the bright ferrite. The fact that the nitrogen content of the steel as shown by chemical analysis is increased by the arc-fusion also supports the view that the change which occurs in the structure is due to the

nitrogen. The statement has been made by Ruder⁸ that metal fused in the absence of nitrogen—i.e., in an atmosphere of carbon dioxide or of hydrogen—does not contain any plates and hence the view that the plates

plates" do not appear to determine to any appreciable extent the course of the path of rupture.

The behavior of the plates under deformation can best be seen in thin specimens of the metal which were bent through a considerable angle. Results of examination of welds treated in this manner have been described by Miller.⁹ Small rectangular plates of the arc-fused metal, approximately $\frac{1}{8}$ in. thick, were polished and etched for microscopic examination and were then bent in the vise through an angle of 20 deg. (approximate).

In Figs. 18 to 21 inclusive are given micrographs illustrating the characteristic behavior of the material when subjected to bending. For moderate distortion the nitride plates influence the course of the slip-bands in much the same way that grain boundaries do—i.e., the slip-bands terminate usually on meeting one of the plates with a change of direction so that they form a sharper angle with the plate than does the portion of the slip-band which is at some distance away (Fig. 18). When the deformation is greater the slip-bands occur on both sides of the nitride plate, but usually show

are due to the nitrogen is very much strengthened. In Fig. 15 the appearance of specimens prepared at the Bureau by arc fusion of electrodes of type "A" in an atmosphere of carbon dioxide is shown. The microscopic examination of the fused metal shows unmistakable evidence of the presence of some plates, although they differ somewhat from those found in nitrogenized iron and in metal fused in the air by the electric arc. Evidently they are due to a different cause from the majority of those formed in the iron fused in air. For convenience, in the remainder of the discussion the "plates" will be referred to as "nitride plates."

RELATION OF MICROSTRUCTURE TO THE PATH OF RUPTURE

The faces of the fracture of several of the tensile specimens after testing were heavily plated electrolytically with copper so as to preserve the edges of the specimens during the polishing of the section and examined microscopically to see if the course of the path of rupture had been influenced to an appreciable extent by the microstructural features. In general, the fracture appears to be intercrystalline in type. Along the path of rupture in all of the specimens were smooth-edged hollows, many of which had evidently been occupied by the "metallic globules" referred to above, while others were gas-holes or pores. Portions of the fracture were intracrystalline and presented a jagged outline, but it cannot be stated with certainty whether the needles have influenced the break at such points or not. Fig. 16 shows the appearance of some of the fractures and illustrates that, in general, the "nitride

a slight variation in direction on the two sides of the nitride plate (Fig. 19); this is often quite pronounced at the point where the plate is crossed by the slip-band.

FIG. 24
Same as Fig. 23, but showing interior markings suggestive of "plates" of arc-fused metal. Etched with 2 per cent HNO₃ in alcohol. $\times 500$.

In a few cases evidence of the "faulting" of the plate as a result of severe distortion was noted (Fig. 20). This was a rare appearance, however, because of the unsound nature of the metal.

On account of the inclusions and other features of unsoundness, rupture occurs at such points before the sound crystals have been sufficiently strained to show the characteristic behavior of the plates. Other micrographs show the beginning of a fracture around one of the "metallic globule" inclusions before the surrounding metal has been very severely strained. For this reason the influence of the plates on the mechanical properties of the crystals cannot be stated with certainty. It would appear, however, that on account of the apparently unavoidable unsoundness of the metal, any possible influence of the nitride plates upon the mechanical properties of the material is quite negligible.

Some of the same specimens used for cold bending were torn partially in two after localizing the tear by means of a saw cut in the edge of the plate. The specimen was then copper plated and prepared for microscopic examination, the surface having been ground away sufficiently to reveal the weld-metal with the tear in it. The nitride plates did not appear to have determined to any extent the path taken in the rupture produced in this manner.

EFFECT OF HEAT TREATMENT UPON STRUCTURE

With the view of possibly gaining further information as to the nature of the plates (assumed to be nitride), which constitute such a characteristic feature of the microstructure, a series of heat treatments were carried out upon several specimens of arc-fused electrodes of both types. Briefly stated, the treatment consisted in quenching the specimens in cold water after heating them for a period of ten or fifteen minutes at a temperature considerably above that of the A_c transformation; 925, 950 and 1,000 deg. C. were the temperatures used. After microscopical examination of the different quenched specimens they were tempered at different temperatures which varied from 600 to 925 deg. C. for periods of ten and twenty minutes. The samples which were used were rather small in size, being only $\frac{1}{2}$ in. thick, in order that the effect of the treatment should be thorough, and were taken from

test bars A₁, A₂, AD₁₀, B₁, B₂ and B₃. These represented metal which had been deposited under different conditions of current density. No plates were found to be present in any of the specimens after quenching. Fig. 22 shows the appearance of one of the quenched bars, a condition which is typical of all. The structure indicates that the material comprising the plates had dissolved in the matrix of iron and had been retained in this condition upon quenching. The needle-like striations within the individual grains are characteristic of the condition resulting from the severe quenching and are to be observed at times in steel of a very low carbon content. Fig. 23 shows the appearance of one of the "A" electrodes ($\frac{1}{2}$ in.) quenched in cold water from 1,000 deg. C. Some of the crystals of the quenched iron also show interior markings somewhat similar in appearance to the nitride plates (Fig. 24). These are, however, probably of the same nature as the interior tree-like network sometimes seen in ferrite which has been heated to a high temperature. The striations were found to be most pronounced in the specimens of arc-fused metal which were quenched from the highest temperatures, as might be expected. Braune¹ states that nitride of iron in quenched metal is retained in solution in the martensite. The same may be inferred from the statement by Giesen² that "in hardened steel, it (nitrogen) occurs in martensite." Ruder³ has also shown that nitrogenized electrolytic iron (3 hr. at 700 deg. C. in ammonia) after being quenched in water from temperatures 600 to 950 deg. C. shows none of the plates which were present before the specimen was heated.

The sets of specimens (A₁, A₂, AD₁₀, B₁, B₂ and B₃) quenched from above the temperature of the A_c transformation were heated to various temperatures, 600, 700, 800 and 925 deg. C. In all cases the specimens were maintained at the maximum temperature for approximately ten to fifteen minutes and then cooled

in the furnace. Figs. 25 to 30 inclusive summarize the resulting effects upon the structure. Heating to 650 deg. C. is not sufficient to allow the plates to redevelop, but in the specimens heated to 700 deg. C. a few small ones were found. The effect is progressively more pronounced with the increased temperature of tempering, and in the material heated to 925 deg. C. they are as large and as numerous as in any of the arc-fused specimens. The heating also develops the islands of

pearlite which are not always to be distinguished very clearly in the simple fused metal. The work of Ruder¹¹ referred to above shows that nitrogenized iron which has been quenched and so rendered free from the nitride plates behaves in a similar manner upon heating to temperatures varying from 700 to 950 deg. C.; the plates reappear after a heating for fifteen minutes at 700 deg. C. (or above), followed by a slow cooling. The similarity in behavior of the two is a further line of evidence that the arc-fused metal contains more or less nitrogenized iron throughout its mass.

PLATES REMAIN AFTER LONG ANNEALING

The persistence of the nitride plates was also studied in specimens heated at 1,000 deg. C. *in vacuo* for a period of 6 hr. A set of specimens (one each of test-bars AD_2 , A_2 , AD_{10} , A_{10} , B_3 , B_2 , B_1 , and BD_1) was packed in a "usalite" crucible, and covered with alundum sand; this crucible was surrounded by a protecting alundum tube and the whole heated in an Arsem furnace. A vacuum, equivalent to 0.2 mm. mercury, was maintained for the greater part of the 6-hr. heating period; for the remainder of the time the vacuum was equivalent to 0.1 to 0.2 mm. mercury. The specimens were allowed to cool in the furnace. Ruder¹¹ has stated that 1 hr. heating *in vacuo* at 1,000 deg. C. was sufficient to cause a marked diminution in the number of plates in both arc-weld material and nitrogenized iron and that at 1,200 deg. C. they disappeared entirely.

The results obtained are shown in Figs. 31 to 36 inclusive. In contradistinction to Ruder's work the plates are more conspicuous and larger than before, the oxide specks are larger and fewer in number. Many of the plates appear to have been influenced in their position by an oxide globule. It would appear that the conditions of the experiment are favorable for a migration of the oxide through an appreciable distance and for a coalescing into larger masses. Figs. 32, 34 and 36 all show some cementite at the grain boundaries which resulted from the "divorcing" of pearlite. The oxide is eliminated entirely in a surface layer averaging approximately 0.15 mm. in depth. Only in projections (right-angled corners, sections of threads of the tension bar, etc.), was there any removal of the nitride plates by the action of the continued heating *in vacuo*. This is shown in Fig. 37, which illustrates the removal of the oxide inclusions also. No evidence was found that the small amount of carbon present in the arc-fused metal is eliminated, particularly beneath the surface.

Fig. 6 (page 778) illustrates an interesting exception to the rule that the nitride plates are flat. The general appearance suggests that the "metallic globules" solidified under a condition of "constraint" and that this condition still persists even after the 6-hr. heating at 1,000 deg. C. which the specimen subsequently received.

TABLE I. CHANGE IN NITROGEN CONTENT UPON HEATING

Specimen	Wt. of Sample in Grams.	Average Nitrogen Content, per Cent		
		Before Heating	After Heating in Vacuo.	Loss per Cent
A_2	1.39	0.127	0.062	51
B_1	6.0	0.124	0.078	37
BD_1	1.62	0.140	0.059	57

¹²W. E. Ruder, "Metallurgy of the Arc Weld," *General Electric Review*, vol. 21, p. 941.

Several of the specimens which were heated *in vacuo* (6 hr. at 1,000 deg. C.) were analyzed for nitrogen. The results are given in Table I.

The fact that the specimens lose nitrogen upon heating (although the amount remaining is still many times the nitrogen-content of the metal before fusion), coupled with the fact that the "nitride plates" are larger and more conspicuous after heating than before, suggests very strongly that these plates are not simple nitride of iron. The method used for the determination of nitrogen gives only the "nitride" nitrogen, hence a possible explanation for the change in nitrogen con-

Specimen AD_{10} was heated for 6 hr. in *vacuo* at 1,000 deg. C. The micrograph represents a section of the specimen at one corner. The oxide and "nitride plates" have been removed in the exposed tip of the thread. Etching, 2 per cent alcoholic solution of nitric acid. $\times 450$.

tent is that it has been converted into another form than nitride and may not have been eliminated from the specimen.

THERMAL ANALYSIS OF ARC-FUSED STEEL*

In order to throw further light on the nature of the plates (nitride) found in the metal after fusion in the arc, the thermal characteristics of the electrode material before and after fusion as revealed by heating and cooling curves were determined. Samples of a 3-in. electrode of type "A" and of the specimen A_1 , which resulted from the fusion were used as material (composition in Tables III and VI, CHEMICAL & METALLURGICAL ENGINEERING, Oct. 6, 1920, vol. 23, pp. 677 and 678).

In Fig. 38 are given the curves obtained which show

the characteristic behavior of the arc-fused metal upon heating. The commonly used inverse-rate method was employed in plotting the data; the details of manipulation and the precautions necessary for the thermal analysis have already been described." In Table II are summarized the data shown graphically in Fig. 38.

The principal change to be noted which has resulted

*Credit is due to Howard Scott, assistant physicist, for the work described in this section.

†H. Scott and J. R. Freeman, Bureau of Standards Scientific Paper 348.

from the arc-fusion of the iron is in the A_1 transformation. This is now very similar to the corresponding change observed in a very mild steel (e.g., approximately 0.15 per cent carbon). That the difference in the A_1 transformation of the arc-fused metal as compared with that of the original electrode is not due to an increase in the carbon content is evident from the lack of the sharp inflection of the A_1 transformation ("pearlite point") which would, of necessity, be found in a low-carbon steel. No evidence of the A_1 change was observed for the arc-fused iron within the range of temperature from 150 to 950 deg. C. The change in the character of the A transformation is without doubt

ings) of 6 hr., the maximum temperature being 1,035 deg. C. The transformation apparently is unaffected by the long-continued heating, thus confirming the results described in the preceding section.

In discussing the properties of steel nitrogenized by melting it in nitrogen under pressure, Andrews¹¹ states that it was found possible to extract almost entirely the small quantities of nitrogen by heating a specimen at 1,000 deg. C. *in vacuo* for periods of 1 to 6 hr. The metal used contained 0.16 per cent carbon and 0.3 per cent nitrogen. Thermal curves are given to show that there are no critical transformations in the material; the nitrogen suppresses them. They gradually reappear, however, as the nitrogen is removed by heating the material *in vacuo* at 1,000 deg. C. Several days' heating was required, however, to obtain an entirely degasified product, the carbon being removed also. A further statement is made that a steel of 0.6 per cent carbon content containing 0.25 per cent nitrogen can be brought back to the normal state of a pure steel only by several weeks' heating *in vacuo*.

The results of the thermal analysis add considerable confirmatory evidence to support the view that the plates existing in the arc-fused metal are due to the nitrogen rather than to carbon.

SUMMARY

Microscopic examination of bent pieces of arc-fused metal show that the metallic grains are inherently ductile, even to a high degree. Grosser imperfections, however, are entirely sufficient to mask this mark of excellence.

The view that the characteristic features observed in the structure of the arc-fused iron are due to the increased nitrogen content is supported by several different lines of evidence. These include the likeness of the structure of the material to that of pure iron which has been "nitrogenized," the similarity in the behavior of both arc-fused and nitrogenized iron upon heating, the evidence shown by thermal analysis of the arc-fused metal, together with the fact that, as shown by chemical analysis, the nitrogen content increases during fusion, while the other elements, aside from oxygen, decrease in amount. The characteristic form in which oxide occurs in iron, together with its behavior upon heating, renders the assumption that the oxide is responsible for the plates observed in the material a very improbable one.

Judged from the results obtained, neither type of electrode appears to have a marked advantage over the other. The use of a slight protective coating on the electrodes does not appear to affect the mechanical properties of the arc-fused metal materially in any way. The specimens were prepared in a manner quite different from that used ordinarily in electric-arc welding and the results do not justify any specific recommendations concerning methods of practice in welding.

In addition to the credit given throughout the text to those who have co-operated in various phases of the investigations, the authors wish to acknowledge the help of H. L. Whittemore and R. W. Woodward for the aid in the necessary mechanical testing and to F. H. Tucker for the general chemical analyses made during the progress of the work.

The Disk, Plate and Cylinder Processes for the Production of Carbon Black

Description With Mechanical Details of Disk, Plate and Cylinder Process
Carbon Black Plants—Driving Mechanism and Heat
Variations—Comparison of Processes

By ROY O. NEAL

THE small rotating disk, ring or Blood process was invented by A. R. Blood in 1883 and is extensively used at the present time. The disk upon which the carbon black is deposited is shown in Fig. 1. It is made of cast iron, varies in diameter from 36 to 42 in. and has a 50-in. face. The lava tips are set in a circular piece of 3-in. standard pipe, which is about 28 in. in diameter and contains from eighteen to twenty-four tips. The scraper for removing the carbon is in contact with the disk continuously and is set over a hopper radially with the disk.

A driving gear bolted on the disk, and a pinion meshing with the gear, are attached to the drive shaft by means of a setscrew. The teeth of the pinion are extraordinarily long to allow for expansion and contraction of the entire length of the driving shaft. A shaft base or cap sets in the axis upon which the disk rotates and acts as a guide and support for the driving shaft. It also makes the pipe, that sets on a concrete base and carries the weight of the disk, more rigid and stable. The gear and pinion actuate the disk, which makes one revolution in about 15 min. Details of a wheel, driving gear and pinion, and shaft base are given in Fig. 2. An assembly drawing of a gear and pinion, shaft base and accessories is shown in Fig. 3, although a disk is used of different design than that above described.

The disks are arranged in rows having twenty-one disks per row, with either two or four rows per building, although the latter is the more common practice. One unit plant has from sixteen to twenty buildings, so that there are eighty-four disks per building and 1,532 disks in an 18-building factory.

Each pair of rows has one conveyor and each row has a separate drive shaft extending the entire length of the building. The drive shafts are moved by a gear and pinion, power being transmitted by a 2-in. shaft located in the alley. Fig. 4 shows how the power is transmitted to a building having four rows of disks.

The carbon black is delivered from the buildings and proceeds the same as in the channel process. No gear-shifting machine is employed and the shafting is lighter than in the channel system, as the weight of the material in the condensing buildings of a typical plant using the rotating disk method is about 150 tons.

The quality and yield of the carbon black made by the disk process is approximately the same as that made by the channel method.

THE "PLATE" OR CABOT PROCESS

The plate system was invented by Godfrey L. Cabot about thirty years ago and has two modifications, one consisting of stationary plates 24 ft. in diameter beneath

which are revolving scrapers and burners that are supplied with gas, and the other, using revolving plates 24 ft. in diameter, having stationary scrapers and burners. The first arrangement is chiefly used and is employed at a plant in West Virginia which until recently had the largest output of any factory in the world. This plant had 113 plates and is shown in Fig. 5. This process is also used in Louisiana.

The plates are made of forty-eight segments, sixteen in the inner row and thirty-two in the outer row, the over-all diameter being 24 ft. The plates are perforated with ventilator holes to allow the products of combustion to escape and afford a means of maintaining a draft. The plate is supported by guys which are screwed into a cap having approximately the shape of a very broad truncated cone. This cap rests upon the top of a hollow mast, the joint between the cap and the mast being made gas-tight with asbestos.

The plates are surrounded by a circular building made of corrugated sheet iron and are 26 ft. in diameter. Above each plate is a roof made partly of triangular pieces of sheet iron and partly of four-sided sheets of corrugated iron that extends about two-thirds of the distance up the 16-ft. mast, leaving, therefore, in the center an open space having about one-third the diameter of the plate, through which the products of combustion can escape.

The mast stands in a bed-plate, the upper surface of which carries a groove in which run steel balls as a bearing. Upon these steel balls rests a casting having eight arms projecting outward and upward that fit into the lower ends of struts made of 2-in. pipe. On the outer end of these struts is an angle casting into which the pipe fits, and a horizontal hole which accommodates a horizontal guy rod. Each horizontal guy is connected at the inner end to an octagonal plate which rotates with the burners around the central mast.

FIG. 1. DISK CARBON DEPOSITING SURFACE

The scrapers and burners revolve around the central mast and the burners fit in a gridiron of pipe lying on a circle of $4\frac{1}{2} \times \frac{1}{2}$ -in. bar iron which is bolted to the vertical face of the angle castings. The lamp is fed by two $\frac{3}{4}$ -in. holes in the central mast incased in a gas-box with stuffing boxes and glands above and below. This gas-box revolves around the mast supported on the

collecting box and descends through a vertical pipe into a circular box that discharges downward into a long conveyor which runs beneath the circular boxes and 2 ft. from the center of the ring. The black is carried from several plates by conveyors that bring it to the packing house, in which it is elevated to bins, from which it is dropped into the packing machines.

All the machinery at these plants moves very slowly so that a surprisingly small amount of power is used. Only one 35-hp. gas engine is necessary to operate twenty-two plates. This includes power for conveyors, packing and bolting machinery.

The writer is indebted to Godfrey L. Cabot for a great deal of the information concerning this system.

ROLLER OR ROTATING CYLINDER PROCESS

The roller process was first used by E. R. Blood in 1883, but at first was unprofitable owing to the small yield. Later, however, the operation details were improved and a market for this product, which possesses valuable properties notwithstanding its inferior color, has been created. At the present time this product sells for the highest price of any grade of carbon black and supplies a limited market, being utilized chiefly in making lithographic and embossing inks, and printing ink for half-tone prints.

FIG. 2. DETAILS OF DISK AND DRIVING MECHANISM

eight-horn casting with the burner pipe, radial black box, etc.

The gas line from the regulators is connected to the bottom of the mast, this mast closed above by a cap from which depend the oblique guys. Slightly below the scraper box are the $\frac{3}{4}$ -in. perforations that admit the gas into the gas-box. To the gas-box are connected two $1\frac{1}{2}$ -in. pipes feeding a 4-in. main in which are screwed the $1\frac{1}{2}$ -in. burner pipe extending beneath the surface of the depositing plate. Each 4-in. pipe feeds over fifty $1\frac{1}{2}$ -in. pipes, equidistant from one another and extending to the periphery, the circular depositing plate. The 1-in. pipes carry the lava tips, that are the same as those in the channel or disk process. The two center pipes have sixty lava tips each, and there are 1,265 tips under the entire plate. The burners make one revolution in 8 min.

The black is removed from the plates by scrapers placed radially to the mast. Below the scrapers is a collecting box that carries a screw conveyor, the shaft of which is actuated by a gear and pinion. The gear sits on the mast and the pinion on the end of the conveyor shaft. The carbon is carried to the inner end of the

FIG. 3. DRIVING MECHANISM IN DISK PROCESS

The buildings or benches in this method are from 65 to 100 ft. in length and from 25 to 35 ft. in width, being made of 24-gage straight or V-crimped sheet iron, and wired to a small angle-iron framework. From four to ten buildings are connected to the same driving shaft or source of power.

The gas is reduced in pressure as in other methods and led to each set of rollers or cylinders by means of a $1\frac{1}{2}$ -in. pipe. Some manufacturers place a small disk in the screw union in each distributing pipe before it is connected to the pipe carrying the lava tips in order to regulate the flow of the gas uniformly under each roller. The burner pipe holding the lava tips is from 3 to 5 in. below the cylinders and in most cases is lower than in the channel system. The lava tips are round and have a round perforation instead of a fishtail opening. The flame issuing from the tips is cylindrical. The tips are separated by $\frac{1}{2}$ in. to 4 in., as is shown in Fig. 6.

The rollers are from 3 to 8 ft. in length, having a spider bearing for a $1\frac{1}{2}$ -in. shaft. If made of cast iron they are about $\frac{7}{8}$ in. thick and $8\frac{1}{2}$ in. (outside dimensions) in diameter, weighing approximately 100 lb. The outside of the rollers is machine faced. Some operators use ordinary extra heavy casing in 8- or 9-ft. lengths and place spider bearings by means of countersunk

FIG. 4. SPIDER, GEAR AND PINION

rivets in each end in the center for the shafting. This arrangement is cheaper and makes the plant more independent of the local foundries, although there is a possibility of the cylinders warping, consequently throwing the driving mechanism out of alignment. At a plant using casing no difficulty was experienced due to warping, distortion or scaling by heat.

The scrapers for removing the deposited carbon black are located at the direct top of the rollers or near the top, and run longitudinally the entire length of the rollers. They are in direct contact with rollers and scrape continuously. On one design V-shaped blades

FIG. 5. PLATE PROCESS PLANT

are attached to the opposite ends of downwardly curved metal straps. One of the blades is positioned for contact with one of the rollers and one for another roller. The weight of the straps and blades is borne by the cylinders, and is sufficient to cause the blades to come into close contact with the rollers and perform their scraping function efficiently.

Over the cylinders is located a removable sheet iron hood, provided with apertures for controlling the ventilation within the roller chamber. This hood also protects the cylinders against drafts. Arranged below the cylinders is a trough-shaped hopper contracted at the bottom and designed to shut out the air from the cylinders and to collect the black which is scraped therefrom. A screw conveyor is mounted in the bottom of the hopper and carries the black to the bolting machines, thence to the storage bins, from which it is taken by the packing machines. The hood, hopper and conveyors are supported by an angle-iron frame. Under each hood are nine rollers, three rollers on each shaft. Where 4-ft. rollers are used there are only two rollers on each shaft, and in some designs there are only two sets of rollers to a hopper. There are two rows of hoods and hoppers to the building, with the shafting running the entire width of the building—that is, each shaft will actuate four or six rollers, depending upon the length of the cylinders. The draft is also regulated by slits or slide doors in the building itself. A typical building, then, would have from 196 to 288 rollers, 10,000 lava tips and about twenty-four to thirty-two hoods and the same number of hoppers.

On each shaft, which is made of hollow pipe, a worm gear with about twenty-eight teeth and a pitch diameter of about 6 in. is attached by means of a setscrew. This gear is actuated by a worm 3 or 4 in. in diameter and having about five threads. This makes one revolution every 15 to 45 min., the grade of black determining the rate at which the cylinders revolve. The worm is mounted on a solid steel shaft moved by a chain and

sprocket transmission from the main power line. The conveyors, elevators, bolting machines and packing machines are also connected from the main power shaft, that is actuated by the gas or expansion engine. The power requirements are about the same as with the channel method. Fig. 7 shows details of this system.

GEARS

A large number of gears are necessary in the machinery for making carbon black. Most of the gears used are bevel, since power is transmitted to the conveyors by this type, although spur gears are made use of in power transmission to bolters, scalpers, etc., and worm gears move the cylinders in the roller process and transmit power from reversing gear shift to main drive shaft, that actuates the rack and pinion in the channel system. Fig. 8 shows a typical spur gear and pinion. The letters refer to:

Gear		Pinion		Gear		Pinion	
Pitch* (circular)	= C	c	Diameter of hub	= H	h
Face	= F	f	Outside diameter	= D	d
Bore	= B	b	Length of hub	= L	l
Pitch diameter	= D'	d'	Projection of hub	= P	p

* Diametral pitch is the number of teeth to each inch of pitch diameter. The word "diameter" when applied to gears is always understood to mean pitch diameter.

If the teeth are properly shaped and the linear velocities of the two wheels are equal, then the angular velocities or speeds of rotation are inversely proportional to the number of teeth and to the diameters. Thus a gear that has twice as many teeth as one mating with it will revolve just half as many times per minute.

In ordering standard gears and pinions it is only necessary to specify circular pitch, bore, face and ratio of number of teeth on gear to number of teeth on

FIG. 6. GAS BURNERS USED IN ROLLER PROCESS

pinion. The width of the faces of teeth is generally made two or three times the circular pitch, although there is no standard rule.

A special gear problem characteristic of carbon black industry arises due to the heat changes. This difficulty is solved by using pinions whose facial dimensions are four or five times that of the gears so that should sudden expansion or contraction result in shaft the gear and pinions will still mesh. Should bevel gears be used, contraction might possibly prevent the intermeshing and upon expansion the teeth might break or force shafting out of alignment, causing a waste of power and undue wear upon gears and bearings—in fact, some bevel gears have worn away as much as $\frac{3}{4}$ in. from this cause. Quite frequently a device is resorted to which is not strictly mechanical, but which, nevertheless, gives good results under the wholly peculiar conditions of this industry—namely, a bevel wheel is driven with a spur

The channel, rotating disk and large plate methods give approximately the same yield of black per 1,000 cu.ft. of gas. The roller system produces considerably less carbon than any of the other processes, but the resultant product is much more valuable and is utilized for highly specialized purposes. Table I shows the yield procured by various processes in different fields.

TABLE I. YIELD OF CARBON BLACK IN DIFFERENT FIELDS

Plant No	State	Process	Lb. of Carbon Black per 1,000 cu.ft. Gas
1	Louisiana	Channel, 2-table	0 78
2	Louisiana	Channel, 1-table	0 95
3	Louisiana	Channel, 1-table	0 80
4	Louisiana	Large plate	0 80
5	West Virginia	Large plate	1 10
6	West Virginia	Rotary disk	0 95
7	West Virginia	Roller	0 80
8	West Virginia	Rotary disk	1 00
9	West Virginia	Channel, 2-table	1 12
10	West Virginia	Channel, 1-table	1 30
11	West Virginia	Rotary disk	1 40
12	Oklahoma	Channel	1 20
13	Wyoming	Channel	1 40

The channel system has the advantage that plants can be constructed almost entirely from standard forms, thus making the enlargement of this type of plant convenient. The cost of construction is less than any of the other types of factories.

The large plate method has the disadvantage of requiring special castings which are so large as to entail a greater initial cost of construction. However, they are advantageous when erecting a plant capable of producing a large output in that the power requirements are less than those of the other methods.

TABLE II. COMPARISON OF DIFFERENT METHODS

Plant No	Location	Method	Sq. ft. per Burner Tip	Sq. ft. per Lb. of Carbon Black	Sq. ft. per 100 cu. ft. of Gas Burned
1	Louisiana	Channel, 2-table	0 21	4 87	3 73
2	Louisiana	Channel, 1-table	0 26	4 23	4 04
3	West Virginia	Roller		9 10	7 33
4	West Virginia	Large plate		6 53	7 16
5	West Virginia	Channel, 2-table		5 05	6 75
6	West Virginia	Small disk		5 10	2 90
7	Oklahoma	Channel, 1-table		5 70	5 50

Sq. ft. of depositing surface

The rotating disk process requires a special casting, but has the preference over the channel method in that the plants are more elastic. Part of the disks in a condensing building may be out of order, still the remaining rings will operate and it is not necessary, as in the channel method, to eliminate an entire condensing building.

A plant using the roller system produces the smallest yield and requires the largest depositing surface per lb. of black made and per 1,000 cu.ft. of gas burned (see Table II) of any type of plant. The demand for the product made by this process is small and the present production is sufficient to supply the present demand.

Japanese Matches

The export of Japanese matches, which during the war monopolized many of the world's markets, is now steadily decreasing, says the *Japan Chronicle*. Most of the trade now goes to Hongkong and the southern part of China. Exports during July reached a value of \$84,399, which was a decline of \$25,693 below the previous month and of \$41,126 below July, 1919. Enormous stocks have accumulated on the Kobe market, where the prices in August showed a slight increase over July.

Commercial Retorting of Oil Shales

BY LOUIS SIMPSON

IT HAS been predicted that within two years gasoline will reach the record price of 75c. per gal.

It is known that there are many millions of tons of oil-yielding shales in the United States, distributed not over one or two, but probably over a majority of the states and that money to develop those properties and retort the shale should be readily obtainable.

These premises being admitted, it is natural to ask, Why should there be any scarcity of crude hydrocarbon oil or of gasoline—a fractionated product of crude oil? There can be no effect without a responsible cause or causes. It is therefore necessary to seek the cause or causes.

When the extent of the wealth of the oil-yielding shale deposits began to be appreciated by the officials of the United States Bureau of Mines, these officials widely recommended those interested in the utilization of these neglected natural deposits to use the style of retort that for many years had been successfully operated in Scotland. This unfortunate advice, given in all good faith, has proved to be a veritable stumbling block in the way of the development of the industry, for the following reason: It has been found (and after years of contention it is now generally admitted) that the Scotch style of retort, the result of development influenced by local conditions peculiar to Scotland, is not the most suitable or the most economical form of retort when used under conditions widely and essentially different from those existing in Scotland.

CLAIMS OF THE SCOTCH

The Scotch, because they had made a success of the retorting of the Scotch oil shales, took every opportunity of making it known to the world that the Scotch oil-yielding shales were the only true oil shales, that the Scotch retort was the only possible retort and that the Scotch-trained shale engineer was the only engineer who knew anything about the oil-shale business. These claims, which have no foundation in anything but in the Scotch imagination, have so frightened the capitalist that the necessary capital in sufficiently large amounts has not been available, capitalists preferring to wait until the retort question was settled.

It is now known that Scotch experience, unmodified by other experience, has in the past proved detrimental instead of advantageous when operations had to be conducted under conditions greatly different from those existing in Scotland. It is now admitted that the chemical principles that underlie the process of retorting oil-yielding shales as carried out in the Scotch retort are correct, but it has had to be granted that, in the application of those principles, there is much that can be improved.

Moreover, even were the application of the principles the best when applied to retorts retorting Scotch shales under Scotch conditions, such application might not and probably would not be the best when the retort is required to retort shale of a different character and quality under conditions that are different.

The shale found in Scotland, needless to say, is not, as claimed, the only true oil shale. Any shale that contains "kerogen" is a true oil shale. The base of such shale may consist chiefly of silica, alumina or lime. The shale may contain a small or a large per-

centage of fixed carbon, it may contain nitrogen and potash in comparatively large or in very small quantities. Hence the variations in quality may be and are very wide.

Further, the oil obtained from the shale may be chiefly of a paraffine, or, on the other hand, of an asphalt base or it may be relatively free from sulphur or have a relatively high sulphur content, all factors affecting the value of the oil.

DIFFERENCES AFFECTING COMMERCIAL VALUE OF OIL-YIELDING SHALE

To summarize, differences that affect the commercial value of oil-yielding shale are:

1. Base of the sedimentary deposit, whether silica, alumina or lime.
2. Base of the recovered oil, whether paraffine or asphalt.
3. Relative percentage of sulphur in the oil.
4. Fixed carbon content of the shale, which may be less than 2 per cent or more than 20 per cent.
5. Quantity of oil recoverable, which may be less than 10 gal. or may exceed 75 gal. per ton.
6. Quantity of nitrogen recoverable as ammonium sulphate, which may be less than 20 lb. per ton and may exceed 100 lb. per ton.
7. Quantity of potash recoverable. In only a few cases will it be found profitable to recover the potash content.
8. Spent shale. This generally is of no value, but should the shale be of a lime base it may at times be profitably used in the manufacture of portland cement.

LOCATION AND CHARACTER OF THE DEPOSIT

The location of the deposit may be favorable or otherwise. The deposit may be near a railway or may be at a considerable distance from any railway communication.

It may be necessary to undertake expensive pipe lines, also wharves, with all the attendant expenses of tanks, etc.

It may be necessary to invest much capital in tank cars, while in other cases one or more of these capital expenditures may not be necessary.

As the shale itself differs within wide limits, so also may the character of the deposit.

In Scotland shale has for some years past been recovered by deep mining, some having been mined at a depth of 2,000 ft., at a commensurately high cost for such mining.

The deposits as known to date may be divided:

1. Horizontally bedded deposits, being the top strata of hills, covered by an overburden that can be economically removed.
2. Horizontally bedded deposits, that can be mined from tunnels or adits driven into the hillside. These may be subdivided into those where the roof is good and those where the roof has been badly disturbed, also into those where the shale beds are from 3 to 8 ft. thick and those where the shale beds are thinner than 3 ft. or thicker than 8 ft.
3. Deposits more or less horizontally bedded, forming the bottom of a valley. These can be subdivided as follows: (a) Those covered by a slight overburden. (b) Those where the over-

burden is considerable, yet not too deep to be economically removed. (c) When it is more economical to bypass certain lean beds.

4. Deposits, now vertical in position, which are made available by the erosion of water, making it possible to remove the shale by quarrying or by modified shovel work. These can be subdivided into those that are covered with but slight overburden and those where the overburden is heavy.
5. Deposits, now vertical in position, appearing as bands of shale extending down the sides and the bottom of valleys, being the remains of synclinals, the anticlinal portions of the formation having been eroded.
6. Deposits such as are found in Scotland, that have to be recovered by deep mining, these being subdivided according to the depth that has to be mined.

METHODS OF MINING

Deposits 1, 3, 4 and 5 can all be excavated by the use of steam-operated, or better still, electrically-operated shovels. This method of mining costs considerably less than the method required in deposit 2 and immensely less than that called for in deposit 6. The difference is so great that it is possible that a deposit giving a low yield of oil, but which can be mined by shovels, will prove more remunerative to operate than a deposit which, although it is rich in oil, has to be mined as deposit 2, typical of the Colorado shales, or as 6, typical of the Scotch shales. The difference in the cost of mining and assembling at today's cost may exceed \$2 per ton of shale, which is a profit in itself.

Unfortunately the shovel method of mining cannot economically be undertaken unless the daily tonnage mined is considerable, hence it is necessary that the industry should be undertaken by concerns prepared to expend the capital necessary to construct works of considerable throughput.

EXPENDITURES AND RETURNS

As stated by Martin J. Gavin in his article "Oil Shales and Their Economic Importance," published in *CHEMICAL & METALLURGICAL ENGINEERING*, Aug. 18, 1920: "The oil-shale industry will require the expenditure of many millions of dollars." Mr. Gavin, however, is not correct when he claims that an investor "will probably have to wait for a long time for a return on his investment and that returns will probably be conservative."

There is nothing to warrant such a statement. Given a property, well selected as to location, extent and quality, not only can the industry be put into operation in unusually quick time, but the profits will become available at once upon the retorts being put into commission and the profits may be expected to be very considerable.

It may be that Mr. Gavin may be able to point to instances where this has in the past been the case, but such conditions have resulted from the attempted operations of works that were ill planned and not well thought out. Plants constructed under such conditions were from the first doomed to disaster.

Plants of small throughput cannot be economically operated. A plant to be capable of being economically operated must be so designed that it can be kept in

commission twenty-four hours per day, seven days per week and 365 days per year, or as near this as may be possible. Such a plant must have a staff of experts, competent to at once attend to any difficulties that may arise. Only works with a large throughput can afford to pay the salaries of such a staff.

A plant of 2,000 tons shale per twenty-four hours throughput is the ideal size for most economical operations. Such a plant when properly designed and constructed can be operated at an absurdly low cost per ton as regards wages, as is evident from the following: Taking wages at the average of the high rate of \$6 per man per eight hours, the cost of mining and assembling being excluded, but including crushing, retorting, condensing, attendance in boiler and power house and for spent shale and oil delivery, including also foremen, the total number of men employed per day is but fifty-three. This, at \$6, gives an expenditure of \$318 for 2,000 tons throughput, or about 16c. per ton. The cost of management, chemists and office will require 8c. per ton more, or a total of 24c. per ton. The cost of ammonium sulphate recovery is a varying charge dependent upon the cost of sulphuric acid and upon the yield of the manufactured chemical per ton shale. The cost may be less than 9c. per ton shale or might be more than 20c.

Repairs may be taken as costing 3c. per ton, loss on packages as 2c. per ton, depreciation as 10c. per ton, taxes (not including excess profits tax), insurance and sundries 5c. per ton, making a total of 44c. per ton plus the cost of ammonium sulphate recovery and the cost of mining and assembling.

As previously shown the cost of mining and assembling depends upon local conditions. It may be less than 20c. per ton and it may exceed \$3 per ton. Speaking generally, the whole cost per ton, including mining and ammonium sulphate recovery, may be less than \$1 per ton, while on the other hand, in extreme cases, the cost may exceed \$3 per ton.

As has been already stated, the difference between the cost of operating an ideally located and developed works, retorting shale in an ideally planned and constructed works and one that is not ideally placed, planned or constructed is a handsome profit in itself, and one that would afford the payment of large dividends.

LACK OF EXPERIENCED OIL-SHALE ENGINEERS

There is, however, another reason why capitalists have, in the past, looked with small favor upon oil-shale propositions. Capitalists who deal largely in mining properties are accustomed to employ certain chosen engineers who are called upon to report upon any proposition submitted to them. Until within a comparatively recent rate there have been no engineers on this continent who were capable of correctly making a report upon an oil-shale property. Even today their number is limited. An engineer with a reputation and experience in gold, silver, copper or iron mining is probably about the most unsuitable man to choose to make such a report. To ask a man who has, and justly has, a reputation gained in work he understands to risk that reputation by giving opinions on work he does not understand is not fair, and such men usually find it safer to turn the proposition down. In consequence of the lack of knowledge difficulties are magnified and reasonable possibilities are ignored. It is but human nature to listen to the old adage and "When in doubt, don't."

An oil journal lately published an account of a small retort plant which operated for sixteen hours per day only, "taking advantage of daylight hours," it was stated. The result was as follows:

	Cents per Ton
Mining (open pit) and delivery.....	73 00
Crushing.....	4 50
Power, wages and gasoline.....	12 00
Retorting.....	24 00
Lubricating oil.....	0 25
	113 75

It is to be noted that in the above-presumed cost many charges are omitted. The figures are quoted for the purpose of comparing the cost of a small plant with one operating upon an economical throughput.

	Small Plant, Cents per Ton	Plant of Economical Cents per T
Mining.....	73	20
Crushing.....	4½	2
Power.....	12	3
Retorting.....	24	4
	113½	29

It is certain that up to date the new business of retorting oil shales on the American continent has never had a fair chance. It is certain that it never will have a fair chance until some strong group of capitalists becomes prepared to risk capital in the construction of a plant large enough to retort 2,000 tons of shale in twenty-four hours. If such a plant be built from properly designed and thought out plans it will be proved that when operating upon medium- to high-grade shales, the return will be very much larger than "conservative" and with this additional advantage the return will be assured for many years to come.

COSTS OF THE INDUSTRY

The costs of the industry should be made out somewhat as follows:

1. Removal of overburden or—in case of mining—preliminary work.
2. Drilling and explosives.
3. Excavating and assembling or loading and assembling.
4. Crushing.
5. Retorting and condensing.
6. Power plant, etc.
7. Removal of spent shale.
8. Byproducts recovery.
9. Warehouse and delivery.
10. Gasoline and lubricants.
11. Repairs.
12. Loss on packages.
13. Taxes, insurance and sundries.
14. Management.
15. Depreciation.
16. Amortization.

In a great many cases the cash returns from the sale of the manufactured byproducts will pay not alone the cost of such manufacture but also all the costs of mining and retorting, etc. In all cases it is necessary that the question of byproduct recovery should be examined carefully. This question has already been discussed at length in CHEM. & MET. ENG., vol. 22, p. 20, Jan. 7, 1920.

When the whole cost of mining, of retorting and of recovering and manufacturing the byproducts can be paid for out of the sales of those byproducts, who is there that will dare maintain that the production of oil by retorting oil-yielding shales is not profitable or at the best will only yield "conservative" returns?

Ottawa, Canada.

Fuel Symposium at the Sixtieth A.C.S. Meeting, Chicago

TWELVE papers were presented in the form of Fuel Symposium which had been prepared by a committee of the Division of Industrial and Engineering Chemistry under the chairmanship of A. C. FIELDNER. Four major topics were discussed by the various speakers: (1) Carbonization of coal. (2) Liquid fuel problems, particularly gasoline. (3) The general problem of fuel conservation. (4) The problem of sulphur in fuels. This session aroused a great deal of interest because of the widespread attention being given to fuel matters and urgency of fuel supply in industry at the present time.

CARBONIZATION OF LIGNITE

A paper entitled "Carbonization of Canadian Lignites," by EDWARD STANSFIELD, was presented by Mr. FRENCH, the engineer who has been associated with this investigation, covering the work done jointly by the Department of Mines and the Lignite Utilization Board of Canada. This report described the early small-scale experiments and the later larger-scale tests which have led up to the design and construction in southern Saskatchewan of a plant which is expected to handle two hundred tons of raw lignite per day. The lignites used are available at about \$1.75 per ton at the mine. A typical analysis of the material employed, on a moisture-free basis, is as follows: Water of constitution, 31.8 per cent, volatile, 28.9 per cent, fixed carbon, 34.1 per cent, ash, 5.2 per cent. The heating value is approximately 4,260 calories per gram. From this material the following results are reported:

	Percentage of Weight of Dry Coal	Per cent of Original Heating Value
Water	11.7	...
Gas	17.0	8.3
Crude tar	4.1	6.0
Residue (char)	66.7	78.1
Loss	0.5	7.6

These represent yields of about 3,150 cu.ft. of gas having a heating value of 385 B.t.u. per cu.ft., 5.3 gal. of tar, 910 lb. of residue, and 10.2 lb. of ammonium sulphate per ton of dry lignite treated. The process is developed to a point where the tar is distilled and the pitch from this used as a binder for briquetting the char. The principal object of this work is the development of a solid fuel, therefore less effort has been made upon gas and byproduct recovery thus far. The commercial plant is nearing completion, and it is hoped that operations will begin within a few months.

As a contribution to the discussion of this report, M. P. SCHOCH, professor of the department of chemistry of the University of Texas, presented a discussion upon the utilization of Texas lignites. The effort in this work was to obtain a supply of city gas, and the tendency was, therefore, along different lines than had been described in the Canadian work. Special attention was given to operation of the retorts under pressure. It was found that this gave a higher yield of gas, but at the expense of a lower yield of tar. This result was probably caused by the slower elimination of the vapors from the retort, causing a greater cracking and, therefore, larger gas yield from the otherwise liquid constituents.

The large percentage of carbon dioxide in the gas led to a special effort looking to the removal of this con-

stituent. As a result liquid purification was adopted and very favorable results are reported. From 2,000 to 3,000 cu.ft. of gas per ton of raw lignite was thus obtained with a heating value in the gas approaching 600 B.t.u. per cu.ft. The yield of coke and tar were of the same order as those reported on the Canadian material.

The advantages claimed for the method of handling recommended were: Coke of a good heating value, gas immediately usable for city supply, maximum yield of tar, a cheap retort of large capacity operating under conditions that make for long life, and the production of coke easily handled in briquetting.

FUEL CONSERVATION

H. C. PORTER discussed the general subject of present and future conservation of fuel supplies. Among the means of increasing our fuel resources he suggested the following: Increased use of boiler plant accessories such as feed-water heaters, and other efficiency devices, use of gas instead of coal in steel plants; electrification of railways; development of superpower electric stations; carbonization of coal at the mine; increased carbonization with recovery of byproducts; alternate carbonization and steaming of coke in a single machine for production of a mixture of coal-gas and blue-gas; use of oxygen to enrich water-gas blast (the oxygen to be made with power used at off-peak hours); a lower heating value per foot for city gas supply; elimination of beehive ovens; and other well-recognized means of fuel economy.

The article by HENRY KREISINGER entitled "Byproduct Coke, Anthracite and Pittsburgh Coal as Fuel for House Heating" was presented by title only. Similarly the reports on "The Charcoal Methods for Gasoline Recovery" and the report on "Colloidal Fuels" were not presented in detail. The abstract of the paper on the latter subject by C. A. SHEPPARD included the following comments:

Colloidal fuels is a name given to a distinct class of liquid-to-semi-liquid blended fuels. They were developed in this country during and subsequent to the last two years of the great war. They are composites, in which finely divided carbonaceous solids or semi-solids—various kinds of coal—are so suspended in and blended with liquid fuel oils as to form readily stable and atomizing fuels. They have been developed for burning with the regular types of atomizing burners using ordinary fuel oils, but have also possibilities for use in internal combustion engines of the Diesel and semi-Diesel type.

The machinery for compounding these fuels is simple; it consists of a suitable mill for pulverizing coal, coke, etc., storage and blending tanks for the oil bases, and mixing kettles for compounding the composite fuel. Little modification in existing types of machinery is necessary, and the process is readily made continuous. The cost of manufacture may be reckoned at approximately \$1.50 per ton, inclusive of the fixateur—a substance used in small quantity to stabilize the colloidal fuel.

The following is a brief summary of the properties of colloidal fuels:

1. They are liquid and handle and atomize for combustion like fuel oils.
2. They contain more heat units per gallon than fuel oils.
3. They contain very little moisture and ash.

4. The temperature at which they take fire (flash point) is above 200 deg. F. They are immune from spontaneous combustion.

5. Not only are they vaporless up to high temperatures, thus avoiding explosive mixtures with air, but they may be fireproofed by a "water seal" of an inch or more of water, owing to the fact that they are heavier than water.

6. Hence also they will sink if spilled blazing on the surface of water—i.e., they are self-quenching. Their fire risk is as low as anthracite coal, and far less than bituminous coal or ordinary fuel oil.

7. They are the most compact fuels known. The advantages of this are obvious: increased radius for ships, lessened storage space in crowded cities.

BYPRODUCT COKING

F. W. SPERR, reviewing the byproduct coke situation, summarized the present status of work in this field. He emphasized particularly the trend toward byproduct gas manufacture and away from the production of water gas. The lesser labor requirement per ton of coal handled in byproduct ovens as compared with coal gas plants handling the coal at smaller units is also a factor at present tending to increase byproduct oven operations. The relative economy of beehive and byproduct oven operations was emphasized and the trend for many years past toward byproduct coke for blast-furnace use was pointed out. It was urged that further study should be given to additional applications of coke so that more of our bituminous coal could be handled with byproduct recovery. Utilization of coke breeze by stokers was pointed out as one important contributing factor to the success of coking at the present time. Other factors mentioned were producer gas firing of ovens, use of silica refractories in place of fireclay materials, the extensive application of tar as a metallurgical fuel, etc. It was pointed out that recent byproduct ovens provided for steaming of coke in the oven, thus arranging that almost complete gasification of the solid fuel may be accomplished in what is practically a single operation.

LOW-TEMPERATURE CARBONIZATION

S. W. PARR presented a discussion of low-temperature carbonization, by which he meant treatment of fuel at temperatures below 750 to 800 deg. C. He indicated that up to this temperature he considered essentially only primary products of distillation; secondary products of high-temperature decomposition do not enter materially until higher temperatures are reached. The usual method of rating coals as to cokability depending upon the ratio of oxygen content to hydrogen content is criticized by this author. He pointed out that conditions of treatment of the coal were of greater importance than this ratio, for if temperature is properly controlled the interaction of the oxygen compounds with those compounds which afford the binder for the coke is prevented. He presented one example of a coal badly weathered which was still suitable for coke production by proper temperature control. He advanced the theory that those constituents which are soluble in phenol react upon heating with oxygen compounds to give compounds of variable composition and prevent coking. He emphasized particularly that the sulphur, nitrogen, and oxygen compounds formed seemed to violate the laws of definite compounds as the percentage composition of these compounds varied by small steps, in a way inconsistent with our usual concept of definite composition.

Because of the low heat conductivity of the coke mass

through which heat must be transferred by ordinary systems of coking, this author has undertaken to use the exothermic heat of reaction during coal carbonization to furnish the bulk of the heat required for coking. He refers to the reactions thus as proceeding "autogenously." He expresses two of his conclusions in this particular as follows:

"It is possible to utilize the exothermic reactions inherent in high oxygen coals in such a manner as to secure the autogenous transmission of heat to the center of an otherwise non-conducting mass and under conditions wherein the ultimate temperature attained at any point of the coal mass is not in excess of the prescribed limit.

"The time for autogenous transmission is governed by the speed of the exothermic reactions involved and is estimated to be approximately one-fourth of the time required for heat penetration as obtained under high-temperature conditions."

At the present time Dr. Parr has not proposed any definite industrial processes, but is working on a basis of a discontinuous operation with 35 lb. samples—i.e. on a commercial laboratory scale.

GASOLINE LOSSES

A. C. FIELDNER and associates reported upon extensive tests of motor vehicles for efficiency in gasoline use. These tests make clear the very large losses of gasoline which result from improper carburetor adjustment and careless driving. These tests were those carried out in connection with the investigation of poisonous gases from automobile exhaust which must be cared for in the proposed vehicle tunnel under the Hudson River.

MIXTURE OF NATURAL AND MANUFACTURED GAS

J. B. GARNER urged the use of natural gas for the enrichment of manufactured gas supplies, stating that in his opinion natural gas companies should no longer be permitted to sell natural gas as such but should conserve it for the city supply to supplement the manufactured gas production for these purposes.

COMMERCIAL REALIZATION OF LOW-TEMPERATURE CARBONIZATION

Dr. HARRY A. CURTIS, chief chemist of the International Coal Products Corporation, reported on the Carbocoal process, which has been developed to the point of the installation of a plant having a daily capacity of 350 tons of product, using 500 tons of coal per day. This process was described in *CHEM. & MET. ENG.*, vol. 23, No. 10, Sept. 8, 1920, p. 499.

SULPHUR IN FUELS

The report of ALFRED R. POWELL discussed the factors which affect the sulphur content of coke and of gas produced by the carbonization of bituminous coals. The significance of the different sulphur compounds in the coal upon the distribution of the sulphur in the products is pointed out.

A report on a similar subject was presented by H. F. YANCY and THOMAS FRASER, entitled "The Distribution of the Forms of Sulphur in the Coal Bed." The relations between the relative quantities of pyrite sulphur and organic sulphur were discussed. This work represents a report on a large number of mine samples, particularly those collected in southern Illinois and western Kentucky.

Dr. Allen Rogers Receives the Grasselli Medal

AT THE joint meeting of the American Section of the Society of Chemical Industry and the New York Section of the Société de Chimie Industrielle, Friday evening, Oct. 8, the Grasselli Medal was presented to Dr. Allen Rogers of Pratt Institute.

Presentation Address

BY MARSTON TAYLOR ROGERT

The Grasselli Medal was established by the Grasselli Chemical Co. of Cleveland, Ohio, to be awarded annually for the paper presented before the New York Section of the Society of Chemical Industry which shall, in the opinion of the medal committee, offer the most useful suggestions in applied chemistry. The committee of award, at its meeting Sept. 17, 1920, voted unanimously to bestow the medal for this year upon the honorary secretary of the American Section, Dr. Allen Rogers, for his paper entitled "Industrial Uses for the Shark and Porpoise," printed in the *Journal of this society* for Jan. 31, 1920 (vol. 39, No. 2, pp. 9-10T).

As a personal friend both of the donors and of the recipient of the medal, it will be understood how pleasant I find my task this evening as the official to make the formal presentation.

Dr. Rogers was born in Hampden, Me., May 22, 1876, and was graduated from the University of Maine in 1897 with the degree of B.S. in the chemistry course.

In 1900 he received the degree of M.S. from his alma mater and in 1902 the degree of Ph.D. from the University of Pennsylvania, where he remained for two years as senior fellow and instructor in organic chemistry.

In June, 1904, he abandoned this temporarily, to enter the employ of the Oakes Manufacturing Co., Long Island City, N. Y., as research chemist, where his investigations on problems related to the leather industry led to several patents being taken out by the company.

In September, 1905, he withdrew from the Oakes Manufacturing Co. and returned to the ranks of the teachers, as professor in charge of industrial chemistry at Pratt Institute, Brooklyn, N. Y., the position he still occupies.

For many years Dr. Rogers has made a special study of leathers and tanning, until he is now widely recognized as one of our foremost experts in this important field. Patents have been granted to him for various processes of treating leather, and other patents are pending. His most interesting work in this direction is that recorded in the paper for which the medal is awarded.

In the time of our country's need he promptly and patriotically sacrificed all personal selfish interests and volunteered for military duty, being commissioned Major in the Chemical Warfare Service, where he was put in charge of the industrial relations branch.

Dr. Rogers is the author of a Manual of Industrial Chemistry, in preparation of which he was aided by over forty distinguished collaborators.

It therefore gives your host of friends particular pleasure, Major, to see this medal awarded to one who has for so many years labored so unselfishly for others and who has devoted himself so assiduously and so successfully to the development of that branch of chemical industry to which the paper relates. May it bring to you much happiness, and may it prove an inspiration to yet further achievement!

Acceptance of the Grasselli Medal

BY ALLEN ROGERS

My dear Colonel Bogert: I certainly appreciate your kind words and hope that I may be worthy of all the good things you have said. It was a great surprise to me, I assure you, when I received the information that my paper on "Industrial Uses for the Shark and Porpoise" had been deemed of sufficient merit to warrant recognition for the award of the Grasselli Medal. The commercial utilization of the shark is a matter that has interested me for several years, and if I have done anything to interest others in my friends of the deep, it is of course very gratifying. Sharks have always been considered as scavengers and of no benefit to man. My work, however, has shown me that they have some good points in their favor, and if we take advantage of them I feel confident that a great industry may eventually be established. Already much has been accomplished in this direction. A fairly large plant is in operation at Morehead City, N. C., where the

DR. ALLEN ROGERS

fish are caught, the skins removed, the livers rendered for oil and the flesh converted into fertilizer stock. Another plant is located at Sanibal Island, Fla., and at the tannery in Newark, N. J., about one thousand skins are being treated each week. Plans are now under way for establishing other stations at various points along the Atlantic and Pacific coasts, while the existing plants will be greatly enlarged.

As time goes on and we learn more about these despised creatures we will no doubt discover new uses for the various parts of their anatomy, and who can tell what benefit may then be derived?

I am sorry not to have been able to show some new motion pictures recently taken at the various plants, but hope to do so in the near future. At that time I may have some results of investigation to present. I have, however, a few samples of leather and oil and will be glad to answer any questions after the meeting.

In accepting this medal I wish to thank the Grasselli Chemical Co., through whose generosity the award is made possible. I desire to express my appreciation to the members of the medal committee for their consideration, and I want to thank you personally for the friendship you have manifested and the inspiration you have given to me in making the presentation of this beautiful medal.

Synopsis of Recent Chemical & Metallurgical Literature

Manufacturing Pig Iron From Pyrites Cinders in Electric Furnaces.—In the manufacture of sulphuric acid from pyrites a byproduct rich in iron is obtained which up to now is of very little use due to its high content of sulphur, making it unfit for use in the blast furnace as an iron ore. MARCEL GUÉDRAS gives a description of manufacturing pig iron from pyrite cinders in electric furnaces in the July, 1920, issue of *Technique Moderne*, pp. 301-304, of which the following is an abstract:

The average composition of the pyrites cinders is:

	Per Cent
NiO ₂ ..	3
FeS ₂ ..	94
S (66 per cent iron)	2.75 to 3.5

This is evidently a very rich ore if it could be used. In collaboration with M. Duina, the author has devised a process for the manufacture of pig iron from cinder in the electric furnace.

In the blast furnace the use of pyrites is limited to a maximum of 10 per cent of the charge. It has been possible to increase this percentage after scorifying by a German process which consumes a relatively great amount of fine coke or coal, but the porous cinders obtained still contain 0.5 to 0.45 per cent sulphur.

A more rational process for treatment is by reduction in the electric furnace, a practical and advantageous process when considering the richness of the cinders in iron and the small content of silica.

A very important point, which formerly has not been duly considered by metallurgists, is the physical state of the roasted pyrite. This pulverulent material is spongy and by this fact absorbs great quantities of water. Quite often pyrite cinders after standing some time contain as high as 20 to 22 per cent of moisture.

To obtain a normal and regular treatment of pyrite cinders it is absolutely necessary first to dehydrate them completely, combining this operation with a partial desulphuration; to be later completed by chemical reactions in the reduction furnace. This point constitutes one of the principal specifications of the Guédras-Duina process.

Desulphuration and dehydration is to be followed by agglomeration, since it is necessary that the cinders shall not be charged into the electric furnace in a pulverulent state, as the fine material would sift through the other constituents of the charge, partially escape reduction and, therefore, be lost with the slag. The combined operations of dehydration, desulphuration and agglomeration take place in a gas heated rotary Breuillé kiln. Temperature required is from 1,000 to 1,200 deg. C.

Pyrite cinders with a sulphur content of 2 to 3 per cent when charged into the furnace leave the furnace with a sulphur content of 0.1 to 0.2 per cent; the nodules are strong, but highly permeable to gases, a very useful quality for the subsequent reducing operation.

Reduction takes place in an open top electric furnace, but can also be done in an electric blast furnace when the gases are to be used.

The desulphurating reactions which take place during a reduction are:

(a) A reaction which is proper to all electric furnaces—namely, the action of lime carbon with the formation of calcium carbide. Carbide and lime then react with iron sulphides thus:

(b) Calcium chloride is also added to the charge, and it intensifies the desulphuration of the molten bath as given by the equation

When the formed carbonyl chloride comes in contact with moisture in the furnace atmosphere or after escaping to the air it is rapidly destroyed according to the equation

(c) Adding manganiferous minerals or manganiferous slag to the charge for the introduction of manganese into the pig iron is also of help in desulphurization.

The technique of this process is based upon two distinct ideas:

(1) Absolute necessity to eliminate the moisture completely in a preliminary roast.

(2) Utilization of the desulphurizing action of the electric furnace, which action is increased by the presence of a calculated amount of calcium chloride in the molten bath.

Due to the high content of sulphur in the original material it is practically impossible to have a complete desulphuration by chemical processes only and it is therefore necessary to have a preliminary desulphuration in conjunction with the dehydration.

Calcium sulphide formed in the furnace is very unstable. This instability is correlated to the question of molecular equilibrium between the constituents of the slag.

The miscibility of sulphur in the metal depends upon the concentration of sulphide in the slag and on the tension of the sulphur.

Very little research has been done upon the vapor pressure of sulphur in hot sulphides, and the data reported usually present great discrepancies. A fact well determined is that when a certain quantity of sulphur has passed into the state of calcium sulphide the equilibrium ratio between iron sulphide in the slag and that in the metallic bath is changed and a certain quantity of sulphur passes into the slag. This action is much more pronounced in continuous pig-iron furnaces than in electric-steel furnaces, due to the continuous addition of the slag-forming lime.

The rôle of carbon oxychloride is of great importance. This is best shown by Michalske's reaction, which takes place even in molten baths:

Chlorine in the COCl_2 thus formed displaces sulphur in iron sulphide

or

The advantages of elimination of sulphur by substitution are that the limit of CaS saturation in the slag cannot be exceeded and complete desulphurization of the metallic bath can be realized.

A desirable slag would be calculated to correspond to the formula $\text{SiO}_2 \cdot 2\text{CaO}$ —i.e., a basic silicate, in which

will be found a certain quantity of CaC_2 , considered in itself a very basic substance. However, to lower the melting point of the slag it is advisable to incorporate a certain proportion of alumina and thus figure to an aluminocalcic silicate of the formula $\text{SiO}_2 \cdot \text{Al}_2\text{O}_3 \cdot 2\text{CaO}$.

The reducing agent used may be coke, charcoal or a mixture of charcoal and anthracite.

To produce a ton of pig iron 380 to 400 kg. of coke is required, which corresponds to 218 kg. of carbon, plus what is needed for carburization.

The consumption of energy may be tabulated as follows:

			Calories
Reduction of	930 kg. iron	1,887	1,754,910
Reduction of	10 kg. Si	7,830	78,300
Reduction of	5 kg. Mn	1,730	8,650
Vaporization of	165 kg. H_2O	1,549	255,585
Fusion of	1,000 kg. pig iron	300	300,000
Fusion of	400 kg. slag	500	200,000
Total heat spent..			2,597,445

Heat received:		
Combustion of 212 kg. of carbon \times 8,133	1,724,196	
	873,249	
Losses by cooling and radiation	259,744	
Heat to be furnished by the current	1,132,993	

That is to say, 1,322 kw.-hr. The actual consumption is on the average 2,200 kw.-hr.; the furnace has, therefore, a power factor of 0.6, which is low.

Pig iron obtained by this process analyzes 0.001 to 0.03 per cent sulphur, which of course is excellent. The consumption of electrodes is 14 kg. per ton of pig iron produced. An industrial plant of 3,000 kw. can produce 11,000 tons of pig iron per year and requires 16,060 tons of pyrite cinders.

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Hardening Iron and Steel.—An aniline dyestuff such as auramine and methyl violet is used in hardening wrought iron and steel. The material in powdered form may be mixed with rock salt, saltpeter and carbon, etc., and spread over the article to be hardened; or a solution in ammonia water may be used for quenching. (Br. Pat. 143,510—1919. W. KAISER, Frankfurt-on-Main, July 21, 1920.)

Sulphonic Esters.—Resinous compounds are prepared by the reaction of phenolalcohols with aromatic sulphochlorides containing hydroxy or carboxylic groups or both these groups; mixtures of two or more such sulphochlorides may be used; the reaction is effected in presence of alkali, preferably in slight excess. The products can be converted into soap-like products which can be used as emulsifying agents, or in the manufacture of lubricants from tar oils. Br. Pat. 143,185—1919. See also 143,187—1919. B. MELAMID, Breslau, Germany, July 21, 1920.)

Transformer Oils.—Tar oils dissolved or not in an inactive solvent are oxidized as by bichromate or permanganate mixtures at low temperatures to obtain fluid oils capable of use as transformer oils. In an

example 100 kilos tar oil is stirred for about an hour with bichromate mixture, and allowed to stand until atmospheric temperature is reached. The supernatant oil is separated from the resin deposited, refined with 2 to 3 per cent of 66 per cent sulphuric acid, washed, and distilled *in vacuo*. In a second example, 100 kilos tar oil is dissolved in 100 kilos benzine and treated at 0 to 5 deg. C.; the solvent is distilled off, and the oil treated as in the first example. (Br. Pat. 143,198—1919. M. MELAMID, Breslau, Germany, July 21, 1920.)

Synthetic Ammonia Analysis.—In the synthetic production of ammonia, the gases circulating in the system are, for determining their ammonia content, passed through an absorbent of ammonia and the electrical

conductivity of the resulting solution measured. In a suitable apparatus, the gases pass through a regulating-valve *c* and a flow-meter *d, f* to an absorber *a* supplied with water at a predetermined rate from a vessel *b*; the solution then passes into an electrolytic cell *g* having electrodes *h, i* of platinum, etc., and in circuit with suitable apparatus for measuring the conductivity. (Br. Pat. 143,341—1919. E. K. RIDEAL and A. G. TARRANT, University College, London, July 21, 1920.)

Glucose.—One part of wood is first dried, treated with 1 to 2 parts of 35 per cent hydrochloric acid, and supersaturated with gaseous hydrochloric acid until the acid concentration reaches 41 per cent, the temperature being maintained between 0 and 25 deg. C. It is then allowed to digest at a slightly higher temperature, and finally the surplus acid is removed and the glucose purified by washing and filtration.

The acid treatment is conducted in a series of externally-cooled connected tubes *A*, each provided with a mixer and conveyor *b*, liquid acid being introduced into the upper vessel and gaseous acid into the lower vessels through pipes *F*. The mash is digested for two to eight hours in drums adapted to turn on hollow axes, through which water is circulated so that the temperature is maintained between 8 and 30 deg. C. Excess hydrochloric acid is then withdrawn from the mass, which contains a mixture of glucose and dextrin, by placing the drum in communication with a vacuum vessel containing dilute acid kept at 10 to 15 deg. C. Sufficient water is added to the mash to allow it to be filtered, and the filtrate is concentrated *in vacuo* to free it entirely from hydrochloric acid, which is collected in

the usual manner. The dextrin may be converted into glucose by boiling for about an hour with diluted hydrochloric acid. Specification 107,219 is referred to. (Br. Pat. 143,212—1919. L. TERRISSE and M. LEVY, Geneva, July 21, 1920.)

Treating Hides and Skins, Electric Endosmose.—In tanning or impregnating materials, they are first impregnated with the tanning, etc., liquor by electric endosmose, and are then treated with preferably stronger liquor without electric current, to complete the tanning, etc. The electric treatment may be carried out as described in Specification 19,849—1914, with liquor of density 2 to 3 Bé., and may last 2 to 3 hours. The non-electric treatment may be effected with liquor of density 10 deg. Bé., and its duration may be two days. Suitable tanning material is extract of pine bark, oak, or chestnut. The invention is applicable to the impregnation, with chromium or other metal salts or colloids, of fabrics which have been treated with glue or gelatine. (Br. Pat. 143,921—1919. ELEKTRO-OSMOSE AKT. GES., Berlin, Aug. 5, 1920.)

Copper Sulphate.—Copper sulphate is obtained from raw copper carbonate ore by treating with dilute sulphuric acid until the solution becomes sufficiently rich in copper, and then neutralizing the solution by some untreated copper carbonate ore, and heating to boiling point until its density is about 52 deg. Tw., it being meanwhile maintained in basic or neutral condition, for which purpose copper oxide may be added and air or steam may be forced through the solution to facilitate separation of the precipitated impurities on cooling. The precipitated matter is separated, and, if any impurities remain, the solution may be again boiled and cooled. (Br. Pat. 143,973—1919. J. S. ROSS, Westminster, Aug. 5, 1920.)

Purifying Rock Salt.—Rock salt is purified for table use by first comminuting it into grains of about 1 mm. in size and sifting, and then grading the grains in saturated salt solution according to their specific gravity. By the process of comminution, the more brittle impurities, such as anhydrite, are broken down into fine powder, which is sifted away; while in the grading treatment, the heavier particles, such as the sulphates of calcium and magnesium, collect in the lower part of the grading device and the pure salt in the upper part. The grading devices are of the kind in which an inclined sieve is agitated in salt solution, or in which the comminuted salt is moved against the flow of strong brine. (Br. Pat. 144,022—1919. L. W. DAMMAN, Zwolle, Holland, Aug. 5, 1920.)

Treating Yarns and Fabrics.—Cotton yarn or cloth is treated for rendering the surface thereof smooth, lustrous, soft, suitable for dyeing and incombustible. The material is immersed for from one to fifty minutes in sulphuric acid of 52 to 60 deg. Bé., washed in water, shaken, beaten or stretched to remove adhering or projecting fibers, and immersed for ten to fifteen minutes in caustic soda having a specific gravity of from 8 to 15 deg. Bé. It is then treated with a 3 per cent solution of borax to render the material incombustible, and afterward with a 5 per cent solution of glycerine or with a solution of calcium chloride, glucose or soap. (Br. Pat. 144,083—1920. S. KASHITANI, Osaka-fu, Japan, Aug. 5, 1920.)

Purifying Oils and Fats.—Animal and vegetable oils and fats, such as whale oil and maize oil, are freed from fatty acids so as to give directly and quantitatively a

neutral oil or fat free from soap and a dry alkali soap ready for use, by treatment with dry caustic alkali or calcined alkali carbonate and removal of the water produced by the reaction, as by heat and agitation under reduced pressure or by the addition of calcined sodium sulphate, and taking up the oil in dry solvents such as methylal, ether, methyl acetate, acetone and carbon disulphide, that dissolve only the oil. The solvent may be added at the start or after removal of the water formed. Thorough bleaching of the oil or fat and the soap may be effected by using peroxide or percarbonate in place of caustic alkali or carbonate. (Br. Pat. 144,176—1919. A. G. BLOXAM, London, Aug. 5, 1920.)

Obtaining Textile Fibers From Papyrus.—In the preparation of textile fibers, which may be used as a substitute for hair, from papyrus, the material, after soaking or retting, is subjected to slight mechanical pressure and to an alternating simultaneous right and left hand torsional or twisting movement, in pairs of rollers so arranged that adjacent pairs move axially in opposite directions. The fibers are dried and the loosened incrusting material is removed and may be used as a carrier for the excitors in the fermentation process. To obtain a cleaner fiber, the fibrous material, either before or after the mechanical treatment, may be subjected to a short fermentation. (Br. Pat. 144,249—1919. J. J. GAHLER HERISAU, Appenzell, Switzerland, Aug. 5, 1920.)

Triphenylmethane Dyes.—Triphenylmethane dyes are obtained either by condensing sulphonated aromatic aldehydes with *o*-nitraniline or derivatives thereof having a free *p*-position, or by condensing unsulphonated aromatic aldehydes with *o*-nitraniline or derivatives thereof having a free *p*-position and sulphonating the product. In the second case, the condensation product is a mixture of the product from one molecular part of aldehyde and two molecular parts of *o*-nitraniline with other products which probably result from further reaction of the aldehyde; the crude mixture can be sulphonated or can be separated into its constituents—e.g., by means of hydrochloric acid—before sulphonation. According to examples: benzaldehyde is condensed with *o*-nitraniline and the product is sulphonated, or the product is separated into its constituents by hydrochloric acid, and the separated constituents sulphonated; benzaldehyde *m*-sulphonic acid is condensed with 3-chlor-6-nitraniline. The products dye wool yellow shades. (Br. Pat. 144,658—1919. BADISCHE ANILIN UND SODA-FABRIK, Ludwigshafen-on-Rhine, Aug. 11, 1920.)

Ammonium Chloride; Alkali Manufacture.—Synthetic ammonia is used in the ammonia-soda process, and the ammonium chloride liquor produced is not treated for the production of ammonia, but is evaporated to obtain a separation of sodium chloride at a high temperature, such as 100 deg. C., and then cooled to obtain a separation of ammonium chloride at a low temperature, the heating and cooling to obtain these salts being repeated if desired. The final mother-liquor, which is a cold solution saturated with ammonium and sodium chlorides, may be added to the liquor to be treated for the production of ammonium and sodium chlorides as above described. It is stated that it is advantageous to oxidize a portion of the synthetic ammonia to nitric acid and to use some of the bicarbonate of soda obtained from it to absorb the acid. (Br. Pat. 144,659—1919. BADISCHE ANILIN UND SODA-FABRIK, Ludwigshafen-on-Rhine, Aug. 11, 1920.)

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Process for Treating Complex Zinc Ores.—The treatment of complex ores containing both volatile and non-volatile constituents, such as lead-zinc ores with which are associated copper and precious metals, is a difficult metallurgical problem. Both wet methods of treatment and smelting methods have been proposed. When smelting lead ores containing zinc in a blast furnace it has been necessary to keep the zinc content of the slag below 8 per cent as a maximum and this, together with the building up of zinc oxide accretions in the cooler portions of the furnace shaft when treating ores high in zinc, has limited the zinc content of the charge to about 7 per cent.

L. B. SKINNER of Denver, Col., proposes to treat this type of ore in a reverberatory furnace in such a way that a greater portion of the zinc is volatilized from the charge and subsequently recovered as fume. Ores high in zinc can thus be treated without difficulty. The method consists in preparing a mixture of an oxidized siliceous ore containing iron and sulphur to form a matte from the non-volatile constituents of the ore with an excess of solid carbonaceous material over that necessary to effect the possible reductions of the charge and treating this mixture on the hearth of a reverberatory furnace by the combustion of fuel with a moderate excess of preheated air. The volatile constituents of the ore are reduced *in situ* by the reducing agent and the gaseous products are passed through a regenerative stove to preheat the air used for the combustion of the fuel and the fume recovered in a bag house. (1,350,286; Aug. 17, 1920.)

Process for the Extraction of Lead From Its Ores.—Several methods have been suggested for the hydro-metallurgical treatment of ores for the recovery of lead and silver, and that more generally termed the "brine process," or "acid brine process," has been used on ores, concentrates and for the recovery of lead and silver from electrolytic zinc plant residues.

F. E. ELMORE of Boxmore, England, has been granted a patent on a modification of the "brine process" which has for its object the economical use of reagents. In some ores lead occurs as a sulphate or can be converted into a sulphate by roasting and in this form can be separated from gangue material by leaching with a hot brine solution. If the lead occurs as sulphide a hot brine acidulated with sulphuric acid will produce a solution containing the lead. Under either condition a certain amount of sodium sulphate and sodium acid sulphate is produced, and the solution becomes, on repeated use, less efficient due to the accumulation of sodium sulphate and to the depletion of the sodium chloride. Further, lead salts are produced containing varying proportions of the sulphate and chloride which under certain conditions is a disadvantage. The proposed process consists in the crystallization and separation of the lead salts from the leach solution and then crystallizing sodium sulphate from the lead-free solution by further cooling to about zero deg. C. The sodium sulphate is separated from the brine and dissolved in hot water. This sodium sulphate solution is used at about 100 deg. C. to treat the lead salts obtained from the first crystallization and thus change the lead chloride to sulphate with the regeneration of sodium

chloride. The lead sulphate is separated from this solution also by crystallization. It is possible to obtain a lead sulphate practically free from chlorides by control of the operation. In case the lead salts contain silver, these after separation from the brine are boiled with sufficient water to dissolve the lead chloride; an insoluble residue remains containing practically the whole of the silver. The lead chloride solution is separated from the residue and treated with hot sodium sulphate solution for conversion into lead sulphate. (1,350,959; Aug. 24, 1920.)

Ammonium Sulphate.—A simplified procedure for the recovery of ammonia from coke-oven gas has been devised by BATES TORREY, Jr., of Syracuse, N. Y. The hot gases are sprayed with water in the hydraulic main and the hot water thus obtained is separated from the tar in settling tanks. The gases are further cooled in a scrubber and the residual tar is removed in a tar extractor. The gases now pass through another scrubber which is sprayed with the hot water recovered from the hydraulic main. During this treatment the gases take up the free ammonia in the wash water and carry it along to the saturators. The un-vaporized water from the scrubber is pumped back to the hydraulic main to be used in spraying the raw gas. After a time, due to the repeated circulation of the water, the concentration of fixed ammonium salts in the solution approaches saturation. Provision is therefore made for the periodical removal of a portion of the concentrated solution. This is treated with lime in an ammonia still. The liberated ammonia passes to the saturators. (1,349,393; assigned to the Somet-Solvay Co.; Aug. 10, 1920.)

Purifying Magnesium Compounds.—Magnesium oxide may be separated from many impurities by treating with a boiling solution of ammonium sulphate. Magnesium sulphate is formed, with the liberation of ammonia, which, when passed into a cold solution of $MgSO_4$, precipitates an equivalent amount of magnesium hydroxide. The reaction is thus cyclic.

The reaction may also be applied to magnesium carbonate, in which case ammonium carbonate is liberated and the final precipitate is a basic carbonate of magnesium. (1,348,933; CLINTON E. DOLBEAR of San Francisco, Cal.; Aug. 10, 1920.)

Treating Waste Pickling Solutions.—Waste pickle liquor (from sheet, plate or wire mills) is forced through spray nozzles into a furnace so heated that the temperature at the top is about 1,200 deg. F., while at the bottom it is about 1,500 deg. F. The vapors, which result from the evaporation of the solution and the decomposition of the ferrous sulphate, pass over a catalyzer which converts any SO_2 to SO_3 . They are then condensed in the form of sulphuric. The iron oxide deposited in the furnace is in an extremely fine state of subdivision and hence is of unusual value as a pigment or filler. (1,348,462; ALBERT T. WEAVER of Joliet, ERNEST W. D. LAUFER of Arlington Heights, and EBERHARD VON WINTZINGERODE of Chicago, Ill., assignors to the American Steel & Wire Co.; Aug. 3, 1920.)

Current Events

in the Chemical and Metallurgical Industries

Meeting of the Rochester Section, A. C. S.

Saturday afternoon, Oct. 2, the Rochester Section of the A. C. S. held its first meeting of the year. The event was celebrated by a visit to the New York State Agricultural Experiment Station at Geneva. Here about one hundred chemists from Rochester, together with those of Geneva, listened to a very interesting address by Dr. L. L. Van Slyke, head of the chemistry department of the station.

Dr. Van Slyke gave a résumé of the work of the station, which consisted largely in its early days of routine analysis, but which has since been enlarged in its scope to cover investigation in milk and milk products, animal nutrition, plant foods, soils, fertilizers, insecticides, etc. Special inspection and research work on milk and its products has resulted in bringing this industry to a very much more efficient and higher plane. The first work in chemistry at the Geneva experiment station was carried on by Dr. Stephen M. Babcock, who is now director emeritus of the Wisconsin Experiment Station. The name Babcock is familiar to agricultural chemists the world over. The name Van Slyke is equally well known.

After Dr. Van Slyke's address Richard F. Keeler presented an outline of a method proposed by Dr. Hobart H. Willard and himself for the determination of aluminum in the presence of a relatively large amount of magnesium by measuring the hydrogen ion concentration. He gave a description and demonstration of an apparatus designed for a plant control laboratory by the use of which the amount of aluminum in from four to six samples of magnesium aluminum alloy can be determined definitely by one operator in less than an hour.

An inspection of the laboratories and farms, followed by a dinner at Hotel Seneca, at which there were talks by Dr. L. L. Van Slyke, Dr. R. J. Anderson, Dr. C. E. Kenneth and Byron Grimes completed the day's program.

Industrial Cost Association Meets in New York

The Industrial Cost Association, the object of which is "the standardization of accounting and cost terminology; . . . interchange of average experience between representatives of manufacturers and dealers engaged in similar activities; . . . to act as a clearing house in distributing to all members the development in cost practices to the end that uniformity, once established, may be maintained," held a meeting in New York City, Sept. 27. This organization is one of industrial executives rather than of professional cost accountants. Membership is held by representatives of a wide range of industries; including many which may be classified as chemical and metallurgical. The officers of the organization are M. F. Simmons, of the General Electric Co., president; C. H. Smith, of the Westinghouse Air Brake Co., first vice-president; Roland H. Zinn, of the Tanners' Council, second vice-president, and A. A. Alles, Jr., of the Fawcus Machine Co., secretary-treasurer. These officers, with the following, comprise the directors: Walter Rantenstrauch, Spencer M. Duty, W. H. Moore, W. E. Hundley and G. K. Wilson.

Evaporation Losses in Gasoline

While engineers, chemists and automobile men throughout the country have been bending their best efforts toward developing some liquid fuel as a substitute for gasoline to meet the ever-increasing demands of the fast-growing automotive industry, the United States Bureau of Mines comes forward with the declaration that the entirely preventable losses in the evaporation of gasoline from crude petroleum from the time the petroleum leaves the wells until it arrives at the refineries reaches a total of more than 300,000,000 gal. each year.

These are merely the preventive losses from evaporation alone and do not take into consideration other losses, many of which in part may be avoided. The total loss from evaporation amounts to more than 600,000,000 gal. of gasoline for the country, one-half of which, or 300,000,000 gal. of gasoline, may be saved.

The worst feature of this loss is the fact that the gasoline wasted is the most volatile and consequently the best quality. It follows that the prevention of this loss, which is economically possible, would not only increase the gasoline supply materially but would also increase the general standard of the gasoline.

The bureau shortly will issue careful directions to the oil men as to how this situation may be remedied.

It is estimated that the 600,000,000 gal. of gasoline lost through evaporation each year is worth as a national asset about \$150,000,000.

Bureau of Standards Loses Many Scientists

The Bureau of Standards during September lost sixty-three members of its scientific staff through resignations. These resignations included such men as Mayo D. Hersey, physicist, in charge of the aviation instrument section; Christian Nusbaum, associate physicist of the magnetic measurement section; A. H. Taylor, associate physicist, in charge of the photometry and illuminating engineering section; Samuel R. Parsons, associate physicist, of the aeronautic power plant section; Victor R. Gage, mechanical engineer, of the aeronautic power plant section; G. M. Williams, associate engineer, of the cement, sand and stone section; William B. Brown, associate physicist, of the aeronautic power plant section; Herbert M. Freeman, associate physicist of the radio section; and Albert B. Peck, associate physicist of the cement, stone and sand section.

Citations by the Federal Trade Commission

The Federal Trade Commission has recently cited the following firms for unfair competition: The United States Color & Chemical Co., Inc., Boston, Mass., for giving cash commissions to employees of its customers to induce their employers to purchase respondent's products; the Seymour Chemical Co., Providence, R. I., for giving to boss finishers in textile mills cash commissions to influence such finishers to induce their employers to purchase the products of the respondent and refuse to buy competitors' goods.

Industry and the Tariff Commission

Need for careful study of industries and commerce before tariff rates are fixed was pointed out with unusual clearness in an address before the Southern Tariff Congress at New Orleans on Oct. 12 by William S. Culbertson, a member of the U. S. States Tariff Commission. "In our complex industrial system," said Mr. Culbertson in his address, "literally thousands of products, many of which are unknown to the average man, are affected by tariff legislation. Unless the data regarding them are gathered by specialists working day after day away from the stress of tariff hearings there can be no adequate understanding of the problems which they raise, either in detail or in their larger bearings on our national welfare."

Since the chemical industries are very vitally concerned with the tariff, a considerable portion of Mr. Culbertson's address dealt with chemical matters. Extracts from his remarks are as follows:

The elimination of Germany from the world's markets by blockade, the diversion of the productive capacity of the Allies to war needs, and the interruption of shipping—each had its constructive effect on our industries.

You may read in the reports of the Commission the records of this progress—of the production of surgical instruments, optical glass, laboratory glassware, scientific instruments, knitting-machine needles, potash, war metals such as tungsten and manganese, and thorium nitrate and incandescent gas mantles. You will find that while some crude barytes was produced in Missouri before the war, the Eastern manufacturers of lithopone—an important paint pigment—imported at that time this raw material from Germany. High prices opened additional barytes deposits in Georgia, Tennessee and Kentucky, which are now supplying not only the Eastern lithopone plants, but also the new barium chemical industry—another child of war conditions. You will learn of the rapid development of the ferro-alloy industries in the United States and of the competition which they are now facing from British sources. You—at least some of you—will no doubt be more interested in the story of vegetable oil production. The increase in the production of peanut oil is most striking. Domestic production increased from 60,533 gal. in 1912 to 12,791,200 gal. in 1918. Most of the imports since 1915 have come from the Orient. Peanut oil, however, is properly considered as a part of the larger problem of vegetable oils, of which there are, as you know, many. Cottonseed oil, coconut oil, soya bean oil and corn oil are only a few of the products that come in more or less close competition with peanut oil. We have attempted to analyze the whole situation in a survey as yet unpublished.

The coal-tar chemical industry may be discussed at greater length as an example of these new developments, partly because it is the most striking and also because of its vital relation to our industrial and military security.

In the meantime the American dye industry was beginning to grow. It was given a stimulus by the tariff act of Sept. 8, 1916, and from that time on until we entered the war the American consumers' needs of the simpler dyes were gradually met. The tariff law of Sept. 8, 1916, served its purpose in encouraging capital to enter the industry. The entrance of the United States into the war brought far-reaching changes in the dye business. On the one hand it restricted the supply of certain raw materials which were commandeered for munition purposes, and on the other hand it forced the dye industry to supply an unusual amount of dyes for the khaki uniforms and thereby decreased the supply of the ordinary colors used by civilians. The industry, however, continued to develop. The production of dyes had increased from about 7,000,000 lb. in 1914 to a total output in 1918 of 58,464,446 lb., valued at \$62,026,390. The growth of this industry reads like a fairy tale.

The signing of the armistice brought new problems for this new industry. During the war the German industry continued partial production and with its productive capacity intact was ready to attempt to regain

its lost markets. The industry had grown in Japan, Great Britain, France and Switzerland. Competition of a serious character threatened the American industry from abroad. Congress has been urged to grant the industry additional protection, not merely because the industry is desirable in a diversified industrial nation, but also because it is vitally connected with the progress of medical science and with the problems of national defense.

The foreign coal-tar dye industry is obviously only one phase of the larger question of the competitive status of foreign industries which we are trying to define. The chief competition with our industries will come in the future, as it has in the past, from Great Britain and continental Europe, but in many lines it will be some time before competition will reach its maximum strength. Speaking generally, wages in Europe, while still lower per man than in the United States, have increased relatively more. The difficulty of obtaining adequate fuel and essential raw materials also contributes to the abnormal cost of production. Transportation is demoralized. The advantage which depreciated currency gives the European producer in selling his goods abroad is very largely offset by the necessity of paying an exchange premium on imported products—coal, raw materials and semi-finished products.

Non-Metals Experiment Work

A limited amount of non-metals work is to be done at the new Bureau of Mines experiment station at Tuscaloosa, Ala. The principal work of the station is to be on byproduct and ferrous problems. The hope is expressed at the bureau that this station will be the nucleus of a much larger station which can give really comprehensive attention to byproducts.

The fear has been expressed that if any non-metals work were done at the Tuscaloosa station it would militate against the chance of securing a non-metals station next year. There was great disappointment among the chemical industries, which are large consumers of the non-metals, that they did not secure one of the experiment stations established this year. They are pointing out that the very limited amount of non-metals work being done at Tuscaloosa is not commensurate with the needs. Attention is being called to the fact that Tuscaloosa is just on the fringe of non-metals territory and is not the logical location for a non-metals station. The idea seems to be very generally held that Knoxville is a well-situated point for a full-fledged non-metals station.

A.S.M.E. Organizes Materials Handling Section

Four hundred members of the American Society of Mechanical Engineers have organized themselves into a Professional Section on Materials Handling and will provide primarily a common channel of intercourse among all the technical and industrial organizations co-operating in the solution of engineering problems connected with the handling and distribution of materials and products.

Probably the greatest economic need of civilization today is the devising of means and a more intelligent application of proper and co-ordinated methods whereby materials of one kind or another may be handled more swiftly and to better advantage.

This Section will aim to be a bureau of information—complete in its scope, specific in its knowledge of the physical and economic conditions and unbiased in its conclusions. This will be done by having special meetings on particular subjects, meetings jointly with other sections, other organizations or associations, and by taking part in all local and national problems relating to the purpose of this Section.

Imports and Exports of Chemicals

Exports of chemicals during August were practically in the same volume as the exports in August, 1919. On the other hand, imports of chemicals were nearly three times as great in August of 1920 as they were in August of 1919. Figures just compiled by the Bureau of Foreign and Domestic Commerce show that chemicals to the value of \$21,189,777 were imported in August of this year. The imports in August, 1919, were valued at \$7,964,651. The value of chemicals exported in August was \$11,296,042. This compares with \$11,121,531, the value of exports in August of 1919. For the first eight months of 1920 chemicals were exported to the value of \$117,929,208. This is materially in excess of the value of chemicals exported during the first eight months of 1919, when they amounted to \$86,350,599. The imports during the first eight months of 1920 reached the large total of \$147,634,259. This compares with \$73,112,471 in the first eight months of 1919.

The total imports of coal-tar products during August, 1920, were valued at \$1,608,672. Switzerland continues to be the heaviest exporter. During August the colors and dyes imported from Germany were valued at only \$54,115. The imports of gums were high in August, amounting to 12,182,391 lb., as compared to 5,513,559 lb. in August of 1919. The same is true of potash. The imports in August of 1920 amounted to 3,389,114 lb. In August of 1919 the imports totaled only 757,102 lb.

The exports of acids were much lower in August of 1920 than they were in the preceding August. The value of the acids exported in August of 1920 was \$365,639. In August the year before the exports of acids were valued at \$519,871. There was a marked increase in the amount of dyes and dyestuffs exported in August, 1920. The total was \$2,111,095. In August, 1919, the total was \$1,172,087. In this particular China was our best customer, with the United Kingdom and Canada in second and third places respectively. The exports of soda in August, 1920, were valued at \$2,156,643. This compares with \$1,771,283 in August, 1919.

Imports and exports of certain chemicals which do not move in large volume are shown by the following table:

EXPORTS CHEMICALS

	Aug., 1919	Aug., 1920
Copper, sulphate of (blue vitriol), lb.	904,110	58,429
Formaldehyde (formalin), value	\$122,978	\$329,146
Glycerin, lb.	391,154	257,057
Salt soda, lb.	1,196,758	643,121

IMPORTS CHEMICALS

	Aug., 1919	Aug., 1920
Ammonia, muriate of, lb. (duty)	213,076	734,361
Fusel oil, or amyllic alcohol and butylalcohol, lb. (duty)	461,443	355,133
Iodine, crude, or resublimed, lb. (free)	72,555	96,528
Lime, citrate of, lb. (duty)	262,483	444,692

Disabled Ex-Service Men Take Up Chemical Engineering

Disabled ex-service men to the number of 107 are pursuing courses in chemical engineering under the vocational education statute. At the end of August there were 1,949 disabled ex-service men taking engineering courses. This instruction is being given under the direction of the Federal Board for Vocational Education.

The work in chemical engineering is divided among forty-six schools, of which four are in New England, thirteen in the East, six in the South, fifteen in the Middle West, and eight in the West.

Apparatus Standards and Reagent Packages

Gas analysis apparatus standards and uniform packages for guaranteed reagents were discussed by two important conferences held in New York during the week of the Chemical Exposition. The committee on guaranteed reagents and standard apparatus appointed by the American Chemical Society is working actively under the chairmanship of W. D. Collins, and just now is giving particular attention to these subjects.

The appropriate size of units for purchase of reagent chemicals was discussed at a conference attended by representatives of manufacturers of guaranteed reagents and members of the committee. A plan was outlined by which the committee will take steps toward greater uniformity in ordering reagents. A tentative list of suggestions along this line will be drafted in the near future and submitted by publication for the criticism and comment of all interested parties.

The committee also called a special conference on gas analysis apparatus which was attended particularly by representatives of laboratory groups which make many gas analyses, both research and routine in nature. A program was adopted tentatively for preparing a set of uniform specifications for certain much used types of gas analysis apparatus. Tentative specifications will be adopted by this sub-committee and submitted to the main committee, which, it is expected, will publish them for comment and criticism before they are recommended for adoption.

Leather Waste for Heels in Germany

Commercial men who are interested in the leather trade are bringing out of Germany samples of a sole leather made from waste leather which is suitable for the manufacture of heels for shoes of all kinds, reports Consul-General Anderson of Rotterdam. The samples produced show a very firm, hard sole leather at first appearance suitable for any purpose for which sole leather is required. It is found upon close examination, however, that the leather is made up of pieces of waste leather which are likely to come apart when wet. The leather is manufactured from waste and scrap leather from old shoes or any other kind of leather waste, and is cleaned and soaked in water and then rolled into sheets and subjected to high pressure. The product has the appearance of a hard, dry, closely pressed sole leather, and for all purposes in shoe-making, when it can be protected to some extent from soaking or can be fastened together as in the nailing of a heel, it gives promise of being useful and economical. The leather can be had at the present time at 17 German marks per kilo, which at present exchange figures out roughly at about 12½c. gold per lb.

Manufacture of Superphosphates in Uruguay

The Administrative Council in Uruguay is considering a project for the establishment of a factory for the manufacture of superphosphates for use as fertilizers. A cheap supply of acid is guaranteed, and there is a great abundance of bones which are being exported at present at a low price. The project would prohibit the exportation of bones, but this is strongly objected to by the majority of the council, who are in favor of placing a high export duty on bones rather than prohibiting their exportation.

Swedish Market for Soda Sulphate

There is at this time a demand in Sweden for soda sulphate, the paper manufacturers generally being in need of supplies, reports Consul-General Murphy of Stockholm. If American manufacturers of chemicals can promptly satisfy the present demand at reasonable prices a steady market will be assured. The Swedish Paper Mills Association of Stockholm uses on an average 40,000 tons of soda sulphate a year, and the managing director states that orders will undoubtedly be forthcoming as soon as sure sources of supplies are located.

The manufacture of paper in Sweden dates back to the year 1573, when the first mill was established at Klippan. There are at this time eighty mills making all kinds of paper and pasteboard and 171 allied industries. The export of paper from Sweden in 1919 was 139,449 tons, as compared with 128,119 tons in 1918 and 189,612 in 1913.

Wood pulp for paper manufacture is likewise an important and flourishing Swedish industry, its future being assured by the vast timber supply of the country. In 1919 there was 807,761 tons of wood pulp exported from Sweden, the value of which was \$13,649,000. The wood-pulp industry is likewise in need of a steady supply of soda sulphate, the home manufacture being by no means sufficient to supply the demand.

Fertilizer Imports Large

More fertilizer materials were imported in August of 1920 than were brought into the country during the first eight months of 1918 and nearly as much was brought in in that single month as was imported during the first eight months of 1919. The following figures are those of the Bureau of Foreign and Domestic Commerce. They show the value of fertilizer materials imported in August of 1920 to have been \$3,953,893. In the preceding August these imports amounted to only \$934,493. These imports were made up largely of bone dust, calcium cyanamide, guano, kainit, manure salts, and muriate and sulphate of potash.

There was some increase in the exports of fertilizer materials. The value of these materials exported in August, 1920, was \$2,967,610. In August, 1919, these exports were valued at \$2,318,420. Phosphate rock led the list of exports, with sulphate of ammonia in second place.

Shale-Oil Prospects in New Brunswick

As the demand for mineral oil is increasing, the visible supply diminishing and the oil companies scouring the world for new sources of supply, interest in oil shales has been revived, reports Consul Rasmussen of New Brunswick, Canada. The oil-shale areas of Albert County, New Brunswick, have recently been inspected by representatives of both British and American interests. According to the Dominion Department of Mines, samples taken from Albert County have yielded 60 imperial gal. to the ton. The concession for the development of natural gas in this same area is held by the New Brunswick Gas & Oil Fields (Ltd.), of Moncton, whose activities are confined to the development of natural gas, but it is possible that shale-oil production will be attempted in the near future either by this company or by other interests.

Decree Modifying the Price of Alcohol in France

The French Ministry of Industry, Labor and Provisions, in accord with the excise administration and the Minister of Finance, has just issued a decree modifying the prices of alcohol. The new prices, as from Sept. 1, are:

For motive power, manufacture of artificial silk and other use in which alcohol is entirely denatured, 100 deg., 3 fr. the liter (1 liter — 1.057 qt.).

For anatomical or scientific preparation, antiseptic and medical use, manufacture of pharmaceutical products, antiseptic and medicated cotton, felt and hats, manufacture of peptone, fulminate of mercury, colloid, artificial flowers, transparent soap, imitation leather, tannin, pyrotechnical products, smokeless powder and aniline colors, 100 deg., 5 fr. 20 centimes the liter.

For the manufacture of vinegar, to Oct. 31, 1920, 7 fr. 60 centimes; from November, 1920, 5 fr. 60 centimes the liter; manufacture of varnish, 5 fr. 72 centimes; perfumery, 13 fr.; university laboratories and official establishments, 21 fr. 80 centimes. For laboratories other than official, medical and pharmaceutical use, use in hospitals and clinics, and for fruits and confectionery and other uses, 21 fr. 85 centimes.

British Firm Makes Grant for Scientific Education

At a recent general meeting of the firm of Brunner Mond & Co. (Ltd.), chemical manufacturers, held in Liverpool there was passed a resolution "that the directors be and they are hereby authorized to distribute to such universities or other scientific institutions in the United Kingdom as they may select for the furtherance of scientific education and research the sum of £100,000 (\$486,650) out of investment surplus reserve account."

Personal

W. M. BITTLE has accepted the position of chief chemist of the Duratex Co., Newark, N. J. He was formerly in charge of pyroxylin investigations.

HARRY A. DEUEL, assistant to the manager of the Minnequa Steel Works and for nineteen years in the employ of the company at Pueblo, has resigned to become chief engineer of the Atlantic Steel Co., Atlanta, Ga.

E. H. FRANTZ, who for the past two years has been plant chemist with the Combination Rubber Co., Bloomfield, N. J. has joined the chemical laboratory force of the Duratex Co., Newark, N. J.

BENJAMIN RICHARD JACOBS has resigned from the Bureau of Chemistry, U. S. Department of Agriculture, to become director of the National Cereal Products Labs., with offices in Washington, D. C.

DYKE V. KEEDY has returned from a six months' trip to Europe, visiting Italy, Dalmatia, Bosnia, France, Holland, Belgium and England.

Dr. ARTHUR I. KENDALL, dean of the Northwestern University Medical School, spoke recently before the Chicago Section of the American Chemical Society on "Bacteria as Chemical Reagents."

Dr. VERNON K. KRIEBLE, assistant professor of chemistry at McGill University, succeeds Dr. R. C. Riggs as Scoville professor of chemistry at Trinity College, Hartford, Conn.

WILSON H. LOW, formerly head chemist for the Cudahy Packing Co., Omaha, Neb., has removed to Los Angeles, where his address is 532 South Lorraine Blvd. Mr. Low and his former head assistant, John H. Show, who was a pioneer in the Nebraska potash industry, have opened an industrial laboratory in Los Angeles.

C. W. NEUSBAUM has resigned as chemist at the Holland plant of the American Radiator Co. to accept a position as assistant chemist for the Beech Nut Packing Co., Rochester, N. Y.

WALTER DILL SCOTT has been unanimously elected president of Northwestern University. Prof. Scott has previously held the chair of psychology at Northwestern since 1905. He served as Colonel on the General Staff during the war, being director of the committee on classification of army personnel. He was awarded the Distinguished Service Medal for this work.

Dr. F. W. TRAPHAGEN, professor of metallurgy in the Dakota School of Mines, has returned to Rapid City, S. D., after spending the summer in metallurgical research work for the Denver Metals Co. at its plant at Utah Junction, Col.

Dr. G. S. WHITBY and **Dr. R. M. MCLEAN** have been appointed joint professors of chemistry in the faculty of applied science, McGill University, Montreal.

Current Market Reports

The Iron and Steel Market

Pittsburgh, Pa., October 15, 1920.

It is now universally admitted that the iron and steel market is marked for a general readjustment. The prospect is accepted with much satisfaction by the majority of consumers, and with philosophic resignation by the producers, most of whom probably feel that they have had artificially high prices for a longer time than could reasonably have been expected.

While "readjustment" is universally admitted as being in prospect, or rather as actually begun, there are some divergences of opinion as to the character or course of the readjustment. A greatly decreased demand is admitted, but there is a difference of opinion as to what will follow in the matter of prices. It is all a question of prices of the independent steel producers, since no one suggests that the Steel Corporation's prices, which have been held to the Industrial Board schedule of March 21, 1919, will decline. Some steel producers insist that the independents will pursue the policy of filling the orders they now have, not seeking additional orders at cut prices, whereby the independent output is predicted to drop for the winter to a relatively low rate, possibly 60 per cent of capacity. Those who take what has already occurred in the market as indicative hold the opinion that independent prices will continue to sag, whereby in a few weeks or a very few months at the outside they will be down practically to the Steel Corporation level.

Illustrative of declines that have occurred and of the gaps between Steel Corporation and independent prices, it may be noted that plates, until recently held by independents at 3.25c. as minimum, have lately sold in small lots at 3.10c. and in at least one case at 3c., while the Steel Corporation's price is 2.65c. Structural shapes were held rather uniformly by independents at 3.10c. as minimum, but have recently sold first at 3c. and then at 2.90c., the Steel Corporation price being 2.45c. Merchant steel bars present a different case. Until lately there were some sellers at 3c., but 3.25c. seems to be the regular independent quotation now, mills having advanced their asking prices to protect contracts. The Steel Corporation price is 2.35c. In the past three or four weeks sheets have declined about half a cent a pound, the independent market being now approximately as fol-

lows: Blue annealed, 5c. to 5.25c.; black, 6.75c. to 7.25c.; galvanized, 8.50c. to 8.75c. The Steel Corporation's prices are 3.55c., 4.35c. and 5.70c. respectively, so that while sheets have declined very considerably they would still have a long distance to travel to meet the corporation level. In pipe there is a divergence of only about \$7 a ton, the Steel Corporation having a 57½ per cent basing discount and the independents a 54 per cent basing discount.

PRODUCTION DECREASING

The September report of steel ingot production, presented by the American Iron and Steel Institute, shows a rate for the month of about 42,700,000 tons per annum, or precisely the rate shown for August, that rate having represented an increase of 7 per cent over the July rate. The increase then was due to improved transportation and other physical conditions, and there was a similar improvement in physical conditions for September. The failure of the statistics to reflect increased production in September confirms reports circulated in the month that some works were already curtailing output on account of lessened demand on the part of contract customers. This trend is more decided now, and it is regarded improbable that October will show as high a rate of production as September. Such a showing would be impressive, because normally October is a particularly good month for tonnage outputs on account of weather conditions.

PIG IRON WEAK

Pig iron has just given a remarkable exhibition of weakness after a display of strength in August that was plainly seen at the time to be largely artificial. In all districts except Chicago and Birmingham pig iron prices advanced in August, but there was nothing like the usual amount of buying and it was clear that prices were being pushed up by what might almost be called a mere whim of the furnacemen, consumers making purchases only for immediate requirements. September was a dull month in the market, and since the end of September it has been almost impossible to sell pig iron at all. A steel works that had been particularly provident in not buying ahead has been in the market for basic iron, which was firmly established by the August advances at \$48.50 valley, or \$50.46 delivered Pittsburgh. Its first purchase was at \$46 valley, from a middle interest, and since then it has bought 1,500 tons, also from a middle interest, at \$41.96 delivered, equal to \$40 valley, while three producing interests had quoted on the basis of \$42. In determining what is "the market price" the trade is usually disposed to ignore "resales" and from that viewpoint the market has not declined to \$40, though the middle interest that sold 1,500 tons at \$40 had 3,500 tons it was willing to sell at the figure. Certainly the market cannot be quoted at over \$42 valley, when producers quote that price to a prospective buyer and do not effect sales. It was as late as last January that basic, on its upward movement, reached \$40 valley, and thus there has been the abnormal experience of pig iron declining more rapidly than it had previously advanced. Bessemer iron remains nominally quotable at \$48.50 valley, though a recent resale, of iron bought at \$47, was at \$46. Foundry is nominally quotable at \$47 valley.

Declines in pig iron are susceptible of different interpretations. Pig iron had advanced more, relatively, than steel products, and thus a decline in pig iron might be regarded merely as a step towards equalization. The pig iron decline is notable on the other hand in that it occurs while Connellsville furnace coke for spot shipment is still \$17. Such a price would justify a very high price for pig iron, and while it is eleven times the average price in May, 1915, and twenty times the price in 1894, it shows no definite signs of being about to recede, and it is, indeed, supported by the coal market, since coke at \$17 represents little more than the market price of the coal involved plus a charge for conversion.

The Steel Corporation's unfilled obligations decreased during September by 430,234 tons to 10,374,804 tons, equivalent to about nine months of production at 90 per cent of capacity. The August decrease had been 313,430 tons.

The Chemical and Allied Industrial Markets

New York, October 16, 1920.

The dullness which has become almost habitual in this market continues uninterrupted, despite the unloading of small lots on the market that have been held in reserve. Buying interests, as in every other industry, are marking time and the period of this waiting having extended into weeks it seems as if steadiness is looked for rather than an advancement of price. The 1921 contract prices being put in effect by producers verify the opinion that there cannot very well be a general price recession for two reasons—(1) the cost of production has increased so much that an increase is inevitable; (2) in the two years of peace production has not even approached consuming demand, which will prevent the flooding of the market in the event of a surplus. The small amount of business transacted is mostly on odd lots for which concessions are being granted by second hands in order to clear their stocks.

HEAVY CHEMICALS

All grades of *alum* remain firm, as very few offerings are being made. *Ammonia lump*, 5@6c., *potash lump*, 8½@9½c., and *chrome lump*, 16@18c. per lb., are all producers' prices and have not changed for some time. One of the items receiving a sharp increase over 1920 contract prices is *soda ash*, which will be sold on a basis of 2c. per lb. f.o.b. works, compared with former manufacturer's price of 1½@1½c. per lb. The spot market on the other hand declined sharply and the demand is not as keen as it was during the previous week, the new level being around \$2.25@\$2.50 per cwt. The new price on *caustic soda* for 1921 delivery is \$4 per cwt. Inquiry has also fallen off on the spot material, which is available at \$4.25@\$4.50 per cwt., with no anxiety evidenced on the part of buyers to take advantage of these unusually low prices when compared with the recent \$5.60@\$6 price. The pressure being relieved, *sodium nitrite* is being offered around 12@14c. per lb. with enough material in the hands of producers to meet the rather low demand, which is especially felt in the spot market.

COAL-TAR PRODUCTS

The crudes are the one sustaining branch of this market and the firmness which is noticeable in these items is caused by a shortage of material. The market in general remained quiet; among those to recede was *aniline oil*, now listed at 28@33c. per lb. The *salts* also dropped off 1c. to a low figure of 33c. per lb. Both grades of *beta naphthol* underwent a change during the period. *Sublimed*, which has been scarce, was hard to find under 90c., while the *technical*, with little or no interest displayed, fell off 5c. to 60@70c. per lb. The crudes have all remained firm, *phenol* being still available at Government price of 12c., while producers are quoting 1c. per lb. higher. Considerable quantities of *naphthalene*, *flake* and *balls*, having arrived from abroad, the recent high levels have dropped to 10½c. for *flake* and 12½c. for *balls*, with a very slow demand for both grades.

CRUDE RUBBER

The consistent dullness of this market is occasionally broken by spasmodic activity which arises from the small demand for immediate requirements—but even these short interludes are not sufficient to make a favorable impression. The basic cause of this is the absolute lack of demand from tire manufacturers, who have been kept out of the market for the past few months by the acute conditions in their own industry. London reports some buying but also, as here, it is confined to small lots. The revival of the tire industry would certainly check the steady drop of all grades of rubber from a 54c. level for *plantation* to the present 25c. per lb.—but this is not expected for some time, and as a result the recession is nominal, as it is difficult to obtain figures on actual transactions.

NAVAL STORES

No improvement over last week's decidedly dull market has been noticed. In fact still lower prices are being heard,

and despite this condition the local market has shown no tendency to buy. *Turpentine* fell off 10c., to \$1.20 per gal., which practically amounts to a nominal figure, as there is so little material being sold. *Rosins* also fell off slightly, the cheaper grades being listed at \$12.90 and WW at \$13.25. This condition cannot go on much longer, as the supplies are not too plentiful and a general rise throughout the naval stores is looked for soon.

OILS

Linseed oil is the item of particular interest on the list, since it seems that it cannot be disposed of at any price. The new level of \$1 per gal. is attracting as little interest among buyers as did the less favorable prices of recent dates. *Chinawood* held firm during the period and an increase in demand would help greatly to raise the current quotations of 17½@18c. per lb.

The Chicago Market

Chicago, Ill., October 13, 1920.

The long-continued period of weak prices shows no sign of an end, although frequent mention is made of the opinion that things will be better after election. In view of the fact that the present depression in all lines is the effect of powerful economic forces rather than political manipulation the correctness of this opinion is questionable. Steadily increasing imports to the extent that America's favorable trade balance was only \$65,000,000 for the month of August indicate measurably reduced industrial activity for some time to come. It seems that the chemical industry can reasonably expect to share in this reduction of activity.

Purchasing is on a hand-to-mouth basis. The consensus among the members of the Purchasing Agents' Association, now in session here in Chicago, indorses this plan, on the ground that a general price reduction of from 25 to 50 per cent is in sight. Consideration must be given to the fact that the chemical industry has already had its shrinkage in most lines, and that but little further drop is economically possible.

HEAVY CHEMICALS

The long-awaited announcement of contract prices on *caustic soda* and *soda ash* was forthcoming this week, the future of *sal soda* and *bleaching powder* being still in the dark. Spot offerings of *soda ash* range from \$2 to \$2.25 per cwt. with the few holders of second hands being forced to make offerings at a low figure by the reluctance of buyers. Contracts for 1921 are offered on a basis of \$2.42 per cwt. for 58 per cent. *Caustic soda* contracts are announced at \$5.06 per cwt. on 76 per cent. This is almost a dollar above current price, recent transactions in a dull market being reported at \$4.15@\$4.25. Some of the returned goods from Japan are going at \$3.85 or lower. The scarcity of *bleaching powder* has been materially relieved and the price has abruptly declined to 6½@6½c. per lb. *Sal soda*, unchanged at \$2 per cwt., is in reasonable supply.

The market on *alcohol* begins to feel the effect of heightened production in that supplies are easier. Prices are unchanged, *ethyl* grade, 190 proof, being quoted at \$5.65 per gal., *methyl*, 97 per cent, at \$3.40 per gal., and *denatured* at \$1.12. *Iron sulphate* (copperas) is easy in the hands of dealers at about \$2.25 per cwt. for spot. Makers report a heavy volume of advance business at 2c. per lb. *Sodium bicarbonate*, under materially reduced demand, is going for \$2.80 per cwt. or less, transactions being limited to small lots. *Chlorine* in liquid form is firmly held by spot traders at 9½c. per lb. Some contracts are being closed for 1921 at figures ranging around \$8.75 per cwt.

COAL-TAR PRODUCTS

Quiet prevails and, in general, a weak tone is felt in prices. *Aniline oil*, which felt a temporary strengthening a short time back, is again off, 27c. per lb. or less being the prevailing price. *Aniline salt* has also receded 2c. in the past three weeks, 34c. being today's price. *Phosgene*, for no apparent reason, has recently fluctuated sharply, the range being \$1@\$1.25 per lb.

VEGETABLE OILS

Linseed oil shows the effect of the constantly increasing visible supply of flaxseed by steady declines, the much-talked-of bogey of \$1 having been reached. Spot carloads are offered at \$1.05 and jobbers are selling small lots to the trade at \$1.25, in barrels, 20c. lower than a fortnight ago. The resumption of production by some of the *corn oil* producers was immediately reflected by reductions in the market, offerings at 10c. per lb. for crude f.o.b. works going begging. Some business was closed at 1/2¢ less. The general condition of the corn products market is shown by recent reductions in the price of *corn sirup*, now being offered at \$4.65 per cwt., against \$4.90 at the opening of the season. *Peanut oil* slumped further to 11c. for Oriental, in tanks f.o.b. coast, and 16c. for edible, out of Chicago warehouses. Low market on competitive oils has driven the *soya bean* product to cover, coast quotation in sellers' tanks being only 9c. and small lot spots 13c.

FERTILIZER MATERIALS

Lower prices on live stock have materially reduced stockyards receipts, thereby decreasing production of fertilizer products. This is fortunate, as unusually warm October weather has forced demand to a low level. Few price recessions have been permitted by producers, and buyers are content to await developments. It seems probable that some further cuts must be made to induce trading. High-grade *ground blood* is quoted at \$7.15 per unit, high-grade *ground tankage* at \$6.85 and *renderer's unground tankage* at \$5.50. *Ground steamed bone* is \$35@\$38 per ton, and *raw bone meal* about \$50

The St. Louis Market

St. Louis, Mo., October 12, 1920.

The last two weeks have seen several fluctuations in the St. Louis market, some items advancing and other items declining slightly. Producers say that these changes have been brought about merely by the normal course of business and that they do not presage much of a change in the general tone of the market.

The market continues in good shape all around. Production is normal, demand continues satisfactory and stocks are such that practically all orders can be taken care of on normal deliveries. Contract business is moving along satisfactorily, numbers of contracts having been renewed since Oct. 1. Spot business is fairly strong. Producers are confident that the heavy chemical market is well under their control.

There has been a slight slackening of the demand for the 66-deg. *sulphuric acid*, but prices remain firm and producers look for an improvement shortly. This has been caused by closer buying on the part of the oil refineries. The 60-deg. grade is stronger and some lots have been quoted at as high as \$16.50 per ton and 1 1/2¢. per lb. in carboys. The average price ran between \$16 and \$16.50 per ton. The 66-deg. is quoted at \$24 per ton and 1 1/2¢. per lb. in carboys in carload lots. The 98 per cent acid remains firm at \$25 per ton, f.o.b. works, with the market for it quiet. Oleum has registered an advance to \$28.50 per ton from \$27.50 and is in good demand.

Demand for *muratic acid* continues very good, but due to liberal stocks the quotation on carload lots in carboys has dropped to 2@2 1/2¢. per lb., a decline of about 1¢. The price on lots in bulk remains at \$25 per ton.

Sodium bisulphate is in good supply, prices remaining unchanged. The demand continues, at from \$5 to \$6 per ton. Steel plants are said to be buying in this market freely and large orders have been received also from makers of animal foods.

Producers report a steadily increasing demand for *nitric acid*, but no increase in price has been registered. The quotations are \$7 per cwt. on the 36-deg. and \$10 on the 42-deg. Standard mixed acid, consisting of 36-deg. nitric and 61-deg. sulphuric, is firm at 1 1/2¢. per lb. of each acid.

Zinc chloride remains at \$4 per cwt. Phenol is still quoted at 12c. per lb. in lots of fifteen tons or more.

Ammonium carbonate, powder.....lb.	.16 - .16 1/2	.17 - .18
Ammonium chloride, granular (white sal ammoniac) (nominal).....lb.	.15 1/2 - .16 1/2	.17 - .18
Ammonium chloride, granular (gray sal ammoniac).....lb.	.13 - .13 1/2	.13 1/2 - .14 1/2
Ammonium nitrate.....lb.	.10 - .10 1/2	.11 - .14
Ammonium sulphate.....lb.	.07 - .07 1/2	.08 1/2 - .09 1/2
Anhydrous tech.....gal.		5.00 - 5.25
Anhydrous tech.....gal.		4.75 - 5.25
Arsenic, oxide, lumps (white arsenic).....lb.	.13 - .14	.15 - .16
Arsenic, sulphide, powdered (red arsenic).....lb.	.16 - .17	.18 - .19
Barium chloride.....ton	120.00 - 130.00	
Barium dioxide (peroxide).....lb.	.21 - .23	.24 - .25
Barium nitrate.....lb.	.10 - .12	.12 1/2 - .13 1/2
Barium sulphate (precip) (blanc fixe).....lb.	.04 1/2 - .05	.05 1/2 - .06
Bleaching powder (see calcium hypochlorite).....		
Blue vitriol (see copper sulphate).....		
Borax (see sodium borate).....		
Bromine (see sulphur, roll).....lb.	.70 - .90	1.00 - 1.05
Calcium acetate.....cwt.	3.50 - 3.55	
Calcium carbide.....lb.	.04 1/2 - .04 3/4	.04 1/2 - .05 1/4
Calcium chloride, fused, lump.....ton	31.00 - 44.00	35.00 - 45.00
Calcium chloride, granulated.....lb.	.02 - .02 1/2	.03 - .03 1/2
Calcium hypochlorite (bleaching powder).....cwt.	7.25 - 7.50	8.00 - 8.50
Calcium peroxide.....lb.		1.50 - 1.70
Calcium phosphate, monobasic.....lb.		.75 - .80
Calcium sulphate, pure.....lb.		.25 - .30
Carbon bisulphide.....lb.	.08 - .09	.10 - .11
Carbon tetrachloride, drums.....lb.	.14 - .15	.16 - .17
Carbonyl chloride (phosgene).....lb.		1.25 - 1.50
Caustic potash (see potassium hydroxide).....		
Caustic soda (see sodium hydroxide).....		
Chlorine, gas, liquid-cylinders (100 lb).....lb.	.09 - .09 1/2	.10 - .10 1/2
Chloroform.....lb.	.40 - .43	.44 - .47
Cobalt oxide.....lb.		2.00 - 2.05
Copperas (see iron sulphate).....		
Copper carbonate, green precipitate.....lb.	.27 - .28	.29 - .31
Copper cyanide.....lb.		.65 - .70
Copper sulphate, crystals.....lb.	.08 - .09	.09 - .09 1/2
Cream of tartar (see potassium bitartrate).....		
Epsom salt (see magnesium sulphate).....		
Ethyl Acetate Com. 85%.....gal.	1.10 - 1.30	1.40 - 1.75
Ethyl Acetate pure (acetic ether 98% to 100%).....gal.		1.75 - 2.00
Formaldehyde, 40 per cent (nominal).....lb.	.48 - .50	5.25 - 6.00
Fusel oil, ref.....gal.		
Fusel oil, crude (nominal).....gal.		
Glauber's salt (see sodium sulphate).....		
Glycerine, C. P drums extra.....lb.		.26 1/2 - .28 1/2
Iodine, resublimed.....lb.	4.30 - 4.35	4.40 - 4.45
Iron oxide, red.....lb.		.03 - .20
Iron sulphate (copperas).....cwt.	2.00 - 2.25	2.35 - 2.75
Lead acetate, normal.....lb.		.13 - .16
Lead arsenate (paste).....lb.	.11 - .12	.13 - .17
Lead nitrate, crystals.....lb.		.90 - 1.00
Litharge.....lb.	.14 - .15	.15 1/2 - .16
Lithium carbonate.....lb.		1.50 - 1.70
Magnesium carbonate, technical.....lb.	.12 - .13 1/2	.15 - .16
Magnesium sulphate, U. S. P.....100 lb.	3.50 - 3.90	4.00 - 4.50
Magnesium sulphate, commercial.....100 lb.		3.50 - 3.60
Methanol, 95%.....gal.		3.25 - 3.30
Methanol, pure.....gal.		3.50 - 4.50
Nickel salt, double.....lb.		.14 - .16
Nickel salt, single.....lb.		.13 - .14
Phosgene (see carbonyl chloride).....		
Phosphorus, red.....lb.	.50 - .55	.60 - .65
Phosphorus, yellow.....lb.		.35 - .37
Potassium bichromate.....lb.	.34 - .36	.39 - .40

		Carlots		Less Carlots	
		\$0	\$56	\$0	\$56

Zinc oxide, U. S. P.	lb.	.17	.25		
Zinc sulphate	lb.	.03	.03	.04	.06

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities.

Alpha-naphthol, crude	lb.	\$1.25	\$1.35
Alpha-naphthol, refined	lb.	1.50	1.60
Alpha-naphthylamine	lb.	.45	.50
Aniline oil, drums extra	lb.	.28	.33
Aniline salts	lb.	.33	.36
Anthracene, 80% in drums (100 lb.)	lb.	.90	1.00
Benzaldehyde (f.f.c.)	lb.	2.00	2.10
Benzidine, base	lb.	1.35	1.40
Benzidine sulphate	lb.	1.15	1.25
Benzoic acid, U. S. P.	lb.	.85	.90
Benzoate of soda, U. S. P.	lb.	.60	.70
Benzene, pure, water-white, in drums (100 gal.)	gal.	.35	.40
Benzene, 90% in drums (100 gal.)	gal.	.33	.38
Benzyl chloride, 95-97%, refined	lb.	.35	.40
Benzyl chloride, tech.	lb.	.25	.35
Beta-naphthol benzoate (nominal)	lb.	1.50	4.00
Beta-naphthol, sublimed (nominal)	lb.	.90	.95
Beta-naphthol, tech (nominal)	lb.	.60	.70
Beta-naphthylamine, sublimed	lb.	2.25	2.40
Cresol, U. S. P., in drums (100 lb.)	lb.	.18	.19
Ortho-cresol, in drums (100 lb.)	lb.	.23	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	1.10	1.15
Cresylic acid, 95-97%, dark, in drums	gal.	1.05	1.10
Cresylic acid, 50%, first quality, drums	gal.	.65	.75
Dichlorobenzene	lb.	.07	.10
Diethylamine	lb.	1.50	1.60
Dimethylamine	lb.	.90	1.00
Dinitrobenzene	lb.	.30	.37
Dinitrochlorobenzene	lb.	.32	.35
Dinitronaphthalene	lb.	.45	.55
Dinitrophenol	lb.	.40	.45
Dinitrotoluene	lb.	.38	.40
Dip oil, 25%, tar acids, car lots, in drums	gal.	.18	.85
Diphenylamine (nominal)	lb.	.80	.85
H-acid (nominal)	lb.	1.90	2.05
Meta-phenylenediamine	lb.	1.25	1.30
Monochlorobenzene	lb.	.18	.20
Monoethylamine	lb.	2.00	2.40
Naphthalene crushed, in bbls. (250 lb.)	lb.	.12	.14
Naphthalene, flake	lb.	.10	.11
Naphthalene, balls	lb.	.12	.13
Naphthionic acid, crude	lb.	.75	.85
Nitrobenzene	lb.	.14	.19
Nitro-naphthalene	lb.	.40	.50
Nitro-toluene	lb.	.18	.25
Ortho-amidophenol	lb.	3.25	4.25
Ortho-dichlorobenzene	lb.	.15	.20
Ortho-nitro-phenol	lb.	.80	.85
Ortho-nitro-toluene	lb.	.25	.40
Ortho-toluidine	lb.	.35	.38
Para-amidophenol, base	lb.	2.50	3.00
Para-amidophenol, HCl	lb.	2.50	3.00
Para-dichlorobenzene	lb.	.08	.12
Paranitroaniline	lb.	1.10	1.15

Para-nitrotoluene	lb.	1.25	1.40
Para-phenylenediamine	lb.	2.50	2.65
Para-toluidine	lb.	2.00	2.25
Phthalic anhydride	lb.	.60	.70
Phenol, U. S. P., drums (dest.), (240 lb.)	lb.	.12	.20
Pyridine	gal.	2.00	3.50
Rosin, technical	lb.	4.25	4.50
Rosin, pure	lb.	6.25	6.75
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.45	.50
Salicylic acid, U. S. P.	lb.	.45	.50
Salol	lb.	.90	1.00
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.30	.35
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.20	.26
Sulphanilic acid, crude	lb.	.32	.35
Tolidine	lb.	1.70	2.50
Toluidine, mixed	lb.	.45	.55
Toluene, in tank cars	gal.	.35	
Toluene, in drums	gal.	.38	.40
Xylidines, drums, 100 gal.	lb.	.50	.65
Xylene, pure, in drums	gal.	.47	.50
Xylene, pure, in tank cars	gal.	.45	
Xylene, commercial, in drums, 100 gal.	gal.	.32	.35
Xylene, commercial, in tank cars	gal.	.30	

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark	lb.	\$0.33	\$0.38
Beeswax, refined, light	lb.	.34	.37
Beeswax, white pure	lb.	.60	.65
Carnauba, No. 1, (nominal)	lb.	.90	.95
Carnauba, No. 2, regular (nominal)	lb.	.85	.86
Carnauba, No. 3, North Country	lb.	.35	.36
Japan	lb.	.18	.20
Montan, crude	lb.	.14	.15
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.09	.09
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.09	.10
Paraffine waxes, refined, 118-120 m.p.	lb.	.11	.11
Paraffine waxes, refined, 125 m.p.	lb.	.12	
Paraffine waxes, refined, 128-130 m.p.	lb.	.13	.15
Paraffine waxes, refined, 133-135 m.p.	lb.	.16	.17
Paraffine waxes, refined, 135-137 m.p.	lb.	.17	.18
Stearic acid, single pressed	lb.	.20	.21
Stearic acid, double pressed	lb.	.22	.23
Stearic acid, triple pressed	lb.	.24	.25

NOTE—Paraffine waxes very scarce.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940	gal.	\$2.15
Pine oil, pure, dest. dist.	gal.	1.80
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.35
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	.85
Pine tar, ref., thin, sp. gr. 1.080-1.090	gal.	.36
Turpentine, crude, sp. gr. 0.900-0.970	gal.	1.75
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990	gal.	.35
Pine and creosote, ref.	gal.	.52

Naval Stores

The following prices are f.o.b. New York, for carload lots

Rosin B-D, bbl.	280 lb.	\$12.90
Rosin E-F	280 lb.	12.90
Rosin K-N	280 lb.	13.15
Rosin W G-W W	280 lb.	13.25
Wood rosin, bbl.	280 lb.	12.50
Spirits of turpentine	gal.	1.20
Wood turpentine, steam dist.	gal.	
Wood turpentine, dist. dist.	gal.	
Pine tar pitch, bbl.	200 lb.	8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50
Refort tar, bbl.	500 lb.	15.00
Rosin oil, first run	gal.	.72
Rosin oil, second run	gal.	.75
Rosin oil, third run	gal.	.92

Solvents

75-76 deg., steel bbls. (85 lb.)	gal.	\$0.40
70-72 deg., steel bbls. (85 lb.)	gal.	.38
68-70 deg., steel bbls. (85 lb.)	gal.	.37
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.29

Crude Rubber

Para—Upriver fine	lb.	\$0.26	\$0.26
Upriver coarse	lb.	.17	.18
Upriver caucho ball	lb.	.17	.18
Plantation—First latex crepe	lb.	.25	
Ribbed smoked sheets	lb.	.24	
Brown crepe, thin, clean	lb.	.22	
Amber crepe No. 1	lb.	.22	

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls.	lb.	\$0.16	\$0.18
Castor oil, AA, in bbls.	lb.	.17	.17
China wood oil, in bbls. (f.o.b. Pac. coast)	lb.	.17	.18
Coconut oil, Ceylon grade, in bbls.	lb.	.16	.16
Coconut oil, Ceylon grade, in bbls. (nominal)	lb.	.17	.17
Corn oil, crude, in bbls.	lb.	.12	.13
Cottonseed oil, crude (f.o.b. mill)	lb.	.10	.11
Cottonseed oil, summer yellow	lb.	.13	.14
Cottonseed oil, winter yellow	lb.		
Linseed oil, raw, car lots (domestic)	gal.	1.07	
Linseed oil, raw, tank cars (domestic)	gal.	1.00	
Linseed oil, boiled, car lots (domestic)	gal.	1.09	

Olive oil, commercial.....	gal.	3.00	—	3.50
Palm, Lagos.....	lb.	.101	—	.102
Palm, bright red.....	lb.	—	—	—
Palm, Niger.....	lb.	.091	—	.10
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.101	—	.121
Peanut oil, refined, in bbls.....	lb.	.17	—	.18
Rapeseed oil, refined in bbls.....	gal.	1.30	—	1.45
Rapeseed oil, blown, in bbls.....	gal.	1.60	—	1.70
Soya bean oil (Manchurian), in bbls, N. Y.....	lb.	.14	—	.141
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.10	—	.11

FISH

Winter pressed Menhaden.....	gal.	\$0.85	—	\$0.90
Yellow bleached Menhaden.....	gal.	.87	—	.90
White bleached Menhaden.....	gal.	.90	—	.92
Blown Menhaden.....	gal.	1.05	—	—

Miscellaneous Materials

All f. o. b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, N. C.	net ton	\$22.00	—	\$25.00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Connecticut

ANSONIA—The Amer. Brass Co., 55 Liberty St., will build a 1-story, 340x400-ft. copper wire mill. Estimated cost, \$725,000. Work will be done by day labor. Noted Oct. 15.

NEW HAVEN—The New Haven Pulp & Board Co., Green and East Sts., plans to build a 2-story factory addition. Estimated cost, \$50,000. Fletcher Thompson, Inc., 1087 Broad St., Bridgeport, engr.

Illinois

CHICAGO—The By-Products Coke Corp. plans to build several buildings between 110th and 111th Sts. and Baltimore Ave.

Iowa

CEDAR RAPIDS—The Concrete Products Co. has awarded the contract for the construction of a 2-story factory and office building to the John Klepach Constr. Co., 1128 South 3d St. Estimated cost, \$60,000.

Maine

GREAT WORKS—The Penobscot Chemical Fibre Co., 49 Federal St., Boston, has awarded the contract for the construction of a 34x45x109-ft. addition to its pulp and paper plant to the Aberthaw Constr. Co., 27 School St., Boston. Estimated cost, \$125,000.

Massachusetts

FITCHBURG—The Fululah Paper Co., Fululah Rd., has awarded the contract for the construction of a 1-story, 40x100-ft. paper factory addition to Samuel M. Green Co., 293 Bridge St., Springfield, Mass. Estimated cost, \$25,000.

WESTFIELD—The Vitrified Wheel Co., Emory St., will soon award the contract for the construction of a 2-story, 60x102-ft. kiln building. Estimated cost, \$30,000. Frost E. Chamberlain, 390 Main St., Worcester, archit.

Michigan

HAMTRAMCK (Detroit P. O.)—The Jeffrey Dewitt Co., Butler Ave. along the tracks of the Grand Trunk R.R., plans to build a 5-story factory for the manufacture of porcelain ware on Butler Ave. Estimated cost, \$200,000.

Minnesota

CHISHOLM—The Bd. Educ. has purchased a site on 3d Ave. and Chestnut St. and plans to build a 3-story, 150x225-ft. vocational school on same. A chemical laboratory will be installed. Estimated cost, \$250,000. Joseph Austin, pres.

New Jersey

GARFIELD—The De Mattia Bros. plan to build a 90x200-ft. rubber mill here. Estimated cost, \$200,000. R. De Mattia, secy. J. F. Kelley, P. O. Bldg., Passaic, engr.

TRENTON—The New Jersey Tile Co., Muirhead Ave., plans to build a 60x200-ft. plant, to include 3 kilns, press room, slip house, etc., on Brunswick St. Estimated cost, \$30,000. Karno Smith Co., Broad St. Bank, engr.

New York

BROOKLYN—The Amer. Marine Paint Co., Inc., 175 Dwight St., will build a 2-story factory on Richards St. Estimated cost, \$75,000.

SYRACUSE—The Crown Oil Co., 310 West Jefferson St., is building a 1-story, 30x110-ft. gasoline and oil building on Van Rensselaer St. Estimated cost, \$30,000.

Ohio

CLEVELAND—The Brass Co., c/o Allan Sogs. archit., 319 Hippodrome Bldg., plans to build a 1-story, 75x180-ft. foundry and machine shop. Estimated cost, \$100,000.

Pennsylvania

BETHLEHEM—The Traveler Rubber Co. plans to build a 1-story, 25x35-ft. pumping station and 1-story, 20x30-ft. cement house. Estimated cost, \$10,000. J. O. Hunt, 114 North Montgomery St., Trenton, N. J., archit.

PHILADELPHIA—The Staybestos Mfg. Co., Linn and Armat Sts., has awarded the contract for the construction of a 2-story, 60x120-ft. factory for the manufacture of asbestos products on Berkley St. and Germantown Ave. to R. M. Peterson & Son, 5114 Germantown Ave. Estimated cost, \$75,000.

Rhode Island

PROVIDENCE—The Revere Rubber Co., 355 Valley St., has awarded the contract for the construction of a 3-story addition to its rubber factory on Valley and Hemlock Sts., to the Cruise & Smiley Constr. Co., East Ave., Pawtucket. Estimated cost, \$50,000.

Texas

TERRELL—The Chairman of the City Comm. will receive bids until Oct. 25 for the construction of a filtration plant capable of purifying 1,000,000 gal. of water every 24 hours.

Wisconsin

MILWAUKEE—Peter Bogenski, 1139 Grove St., plans to build a 1-story, 70x172-ft. factory for the manufacture of waterproof cement brick.

MILWAUKEE—The Red Star Yeast & Products Co., 27th and St. Paul Sts., will soon award the contract for the construction of a 2-story, 30x36-ft. yeast house. Estimated cost, \$25,000. E. H. Liebert, University Bldg., archit. and engr. Noted Oct. 6.

PORT WASHINGTON—The Turner Mfg. Co. will soon receive bids for the construction of a 1-story, 60x180-ft. foundry, machine shop, etc., on Main St. Estimated cost, \$150,000. W. A. Englehardt, mgr. K. D. Chase, Michigan Ave., Chicago, archit. and engr.

WAUWATOS—The Milwaukee Co. Bd. of Administration received bid for rebuilding the sewage disposal plant from the Lippmann Stone Co., 449 Clinton St., Milwaukee. \$27,904. Noted Oct. 6.

Wyoming

CASPER—The city plans to install a manual-controlled chlorination system in the pumping house here. Estimated cost \$1,500. F. S. Knittle, City Hall, engr.

New Brunswick

GRAND FALLS—The International Paper Co., Three Rivers, will receive bids in November for the construction of a pulp and paper plant here. Estimated cost, \$1,000,000.

Nova Scotia

SYDNEY—The Dominion Iron & Steel Co. will soon award the contract for the construction of a brick-making plant.

Ontario

PORT ARTHUR—The Provincial Paper Mills, Ltd., has purchased the Port Arthur Pulp & Paper Co. and plans to expend \$1,000,000 to improve and build additions to same for its own use. Noted Sept. 15.

TORONTO—The Anthes Fdry Co., Ltd., 64 Jefferson Ave., has awarded the contract for the construction of a 1-story foundry on Jefferson Ave., to the Ramsay Contg. Co., 39 Indian Rd. Estimated cost, \$20,000.

Quebec

MONTREAL—The Sherwin-Williams Co., Ltd., Centre St., has awarded the contract for the construction of a 3-story addition to its plant to Angil Norcross, Ltd., 65 Victoria St. Estimated cost, \$42,000.

THREE RIVERS—The city will submit a bylaw to the ratepayers for the construction of a filtration plant and aqueduct. Estimated cost, \$225,000. Z. Lambert, engr.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1930 meeting Dec. 27, 1930, to Jan. 1, 1931, at Chicago, Ill.

AMERICAN ASSOCIATION OF ENGINEERS will hold a meeting on employment and education in the Congress Hotel, Chicago, on Nov. 12.

AMERICAN CERAMIC SOCIETY will hold its annual meeting the week of Feb. 21, 1931, at Columbus, Ohio, with headquarters at the Deschler Hotel.

AMERICAN ENGINEERING COUNCIL of the Federated American Engineering Societies will hold a meeting Nov. 18 and 19, 1930, in Washington, D. C. Headquarters will be at the New Willard Hotel.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its winter meeting at New Orleans, Dec. 6 to 9. Headquarters will be at the Hotel St. Charles.

AMERICAN MINING CONGRESS will hold its next convention in Denver Nov. 15 to 19.

AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS' 1930 annual meeting will be held in the Engineering Societies' Building from Dec. 7 to 10 inclusive.

CANADIAN INSTITUTE OF MINING AND METALLURGY will hold its second annual Western meeting in Winnipeg, Man., on Oct. 26, 26 and 27. Headquarters will be at the Hotel Fort Garry.

ENGINEERING COUNCIL will hold its next meeting in Chicago, Thursday, Oct. 21.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall national convention at Carnegie Music Hall, Pittsburgh, Pa., Nov. 10, 11 and 12.

Industrial Notes

THE JEFFREY MANUFACTURING Co., Columbus, O., has opened an office at 1108 Marine Trust Bldg., Buffalo, in charge of H. W. Scott, formerly of the Columbus, O., office, in order to render more efficient service to western New York customers.

THE ELECTRIC FURNACE CONSTRUCTION Co., Philadelphia, Pa., announces that its first electrically heated core and mold drying oven has been put into operation at the Emery Steel Castings Co., Baltimore, Md. It is also announced that orders were received for the following Greaves-Etchells electric furnaces: Jollette Castings & Forgings, Ltd., Jollette, P. Q., 1 ton; Brennen Steel Castings Co., Cleveland, O., 1/2 ton. The furnace for the Bird-Archer Co., Cohoes, N. Y., for making special steel castings, has also been successfully started up.

MONSANTO CHEMICAL WORKS announces the establishment of a Chicago branch in the Marine Bldg., 209 North LaSalle St. This branch is opened with a view of serving its customers and friends in Chicago and surrounding territory more efficiently than could be done from St. Louis. A complete stock of the products manufactured by Monsanto Chemical Works will be carried at this branch, which will be managed by W. L. Filmer, who previously had charge of the flavors and condiments division of the St. Louis sales department.

A group of prominent steel foundries comprising: Electric Steel Co., Chicago, Ill.; Fort Pitt Steel Castings Co., McKeesport, Pa.; Isaac G. Johnson Co., Spuyten Duyvil, N. Y.; Lebanon Steel Foundry Co., Lebanon, Pa.; Michigan Steel Castings Co., Detroit, Mich., and the Syver Steel Castings Co., Milwaukee, Wis., have organized for the purpose of developing and perfecting higher standards in the production of steel castings. R. A. Bull, formerly vice-president of the Duquesne Steel Foundry Co., resigned from that position and has been appointed consulting metallurgist for the group mentioned. He will devote his entire time to preliminary research. His connection with the foundry industry covers a period of over twenty years, during which he has held important positions in foundries in St. Louis, Chicago, New York and Pittsburgh. The new organization will undoubtedly be a vital factor in the further improvement of the strength and quality of steel castings.

Shall the Government Patent and Develop The Inventions of Its Employees?

UNIQUE in the cordial relations existing between Government officials and industrial scientists and engineers was the meeting held at the Chemists' Club in New York on the evening of Oct. 15 to discuss certain plans for patenting and developing the inventions of Government employees. Under the auspices of the American Institute of Chemical Engineers, the New York sections of the American Chemical and American Electrochemical societies, and the American Section of the Society of Chemical Industry, Dr. FREDERICK G. COTTRELL, Director of the Bureau of Mines, and Dr. CARL L. ALSBERG, Chief of the Bureau of Chemistry, explained their problems in disposing of inventions of Government employees, made in the course of official duties, and advocated legislation for dealing with these "byproducts" of regular work. A full report of the meeting, prepared from stenographic notes, is published elsewhere in this issue.

We regard the subject as of the utmost importance to industry, because it involves the question of the encroachment of Government on private business. It involves also a new departure in developing patentable inventions made by Government employees, and thus vitally affects the future relations of Government and industry. For these and other evident reasons we commend to the chemically-controlled industries a careful study of the plan outlined by Dr. COTTRELL, as all of them may be concerned in the course of time.

Briefly stated, the thesis of Dr. COTTRELL is this: In the course of their official work in fundamental research, industrial investigations or for the purpose of law enforcement, Government employees inevitably make discoveries and inventions which have actual or potential commercial value, provided they are developed and brought to the point of industrial application. Lacking any suitable machinery for this purpose, these inventions are lost to industry and a valuable byproduct of Government research is neglected. Dedication of the patent to the public is claimed to be futile as far as further development of the idea is concerned, because private industry will not take up and develop an invention on which it has not the protection afforded by a patent or by a license from the patentee.

The remedy proposed is to authorize the Federal Trade Commission to accept assignment of such patents, license their use and collect royalties which are to be paid to the Treasurer of the United States, excepting a part which is to be paid to the inventors whose patents are thus handled. Legislation to this effect has already passed both houses of Congress, in slightly different form in each, and is now in conference committee pending action at the forthcoming session.

It may be surmised that industrial scientists are not pleased with the prospect of thus injecting a new and unknown element into the already highly competitive state of private business—and for a variety of reasons which we believe will increase as knowledge of the plan becomes more widespread. For ourselves we see in the proposal an experiment in economics and patent administration which is not justified in the light of present industrial conditions, and one which is almost certain to lead to friction between Government and business and in many cases an abrupt termination of the cordial relations now existing between certain industries and Government bureaus. While the plan admittedly has not had wide circulation in business and industrial circles, we have failed to find an advocate outside of Government or quasi-public institutions. Is it not a significant fact that the industries which are to be affected in a practical way by this legislation will have none of it, being quite willing to take chances with competitors in developing business but viewing with apprehension the entrance of a third party into the field on a basis which, in the nature of the case, can scarcely be impartial? The whole subject is one that needs more counsel between Government and business before it is finally settled by legislation.

Examination of the bill suggests to us the following objections to its passage: In the first place, rightly or wrongly, business has no confidence in the Federal Trade Commission; and any proposal which places in the hands of that body the power which the present bill confers will be regarded with suspicion. Power once acquired by a governmental agency is not lightly abandoned. More than that, it is likely to be extended as time passes, until the original purport and intention of even an acceptable measure are lost and forgotten. In the present case the success of the plan depends on its administration, and there is no certainty that that would be in accordance with the good intentions of its promoters. Although the latter argue that the bill is an enabling act and not mandatory, and that therefore it will fail if not wisely administered, it would still appear that under its terms the President has the power to direct that all patentable matter resulting from research work in any Government department be patented and administered by the Federal Trade Commission. Thus the United States could become a vast holding company, owning patents affecting practically every branch of private industry.

But granting that the act is wisely administered, we still have the necessity of partiality in its administration, for unless licenses are restricted in number there is no gain over dedication of the patent to the public in the first instance. Thus we will be confronted with the delicate decision as to how many licenses shall

be issued, and still more important, to whom. If such a situation can be handled by the Federal Trade Commission with satisfaction to all concerned an unexpected measure of success will have been achieved. No one believes it is possible. By the terms of this bill the Government is committed in advance to the principle of participation in private business on a selectively competitive basis. Its patented discoveries and inventions will not flow to industry as a whole, but to such units thereof as may be selected. Its non-patented, and presumably inconsequential, discoveries will be open to all as heretofore. It is quite conceivable that the Federal Trade Commission, in order to protect its favored licensees, will have to conduct a lively legal business in suits for infringement against concerns which see fit to ignore the discriminative policy.

In the meantime what about the effect of the bill on the employee in whose interest, in part, the measure has been drawn? Dr. COTTRELL rightly minimizes the reward to the employee as a feature of the bill, and lays principal stress on the benefit to the public by bringing inventions into practical use. But the employee is to profit nevertheless, and we may well inquire into his attitude if the bill becomes law. Will it be humanly possible for him to forget that then there will be some incentive for him to produce patentable inventions? Will there not be the temptation, which may even become an established tendency, to pursue those lines of industrial investigation that will lead to immediate reward, and neglect more fundamental research that could benefit the whole industry without profit to the individual? Putting these questions to a man recently resigned from Government service, he admitted that the existence of such a law would be bound to affect his attitude somewhat. How shall we commercialize the inventions without at the same time and in some degree commercializing the inventors? And how will the scheme be regarded by that employee of the Government whose work is outside the field of patentable invention? Ability and meritorious service are not confined to the scientific bureaus alone; and yet the bill would discriminate between those employees who, as a class, may make and receive reward for patentable inventions and those who, from the very nature of their work, may not. Certainly no private industry would deliberately inject so disquieting and disturbing a factor into its organization, and there is no reason to believe that its effects will be less baneful inside the Government than without.

The measure is admittedly an experiment in economics in order to solve a problem arising in certain Government bureaus. We doubt if the experiment is called for either on account of an accumulation of valuable inventions in those bureaus or for the benefit of the public. Government inventions probably are no better or worse than the average run emanating from industries having research laboratories, and we know that most of them are inconsequential as far as practical development is concerned. If anyone thinks that valuable and practical patents are numerous let him study the patents expiring, say in 1920, which are pertinent to his industry, and see how many he will be inclined to adopt. Those on which he would spend much money will be a surprisingly small, if not fractional, percentage of the whole.

As for the argument that patents dedicated to the public will not be accepted by industry on account of

lack of protection during the development period, there may be another way to make such inventions effective—viz., by promulgating such industrial regulations as will call for the patented article or process. This could be done consistently in the interest of the public, and more impartially than the Federal Trade Commission could grant licenses.

In addition to the foregoing there are many other objections to the legislation, which will be found in our report of the meeting. The subject is a large one and no attempt has been made to exhaust it. We believe that one of the parties at interest—industry—has not been fully advised of the purport of the legislation and consequently has not fully conceived its effects. The printed hearings on the bill reveal no witnesses from industry or from any other source appearing against the measure. Immediate steps should be taken by industrial organizations to inform themselves fully in the matter and to urge rehearings if such are possible. No emergency exists which could be met by immediate passage of the bill, and surely it would be better to have all elements harmonious if such a thing were possible. If industry does not take advantage of this opportunity to make itself heard and felt, then it will have no fault to find with those who, from altruistic and sincere motives and as a result of long study and deep thought, propose experiments in patent administration in the interest of the public. The matter has now received more publicity than all that has gone before and those who will be adversely affected will proceed with their eyes open. They should not only marshal facts in opposition to the plan, but should if possible suggest alternative methods of solving the problem encountered by Government officials. Immediate action is necessary if anything is to be accomplished.

Thoughtless Legislation

IT WILL BE recalled that one of the aims of the National prohibition act as set forth in its title was "to insure an ample supply of alcohol and promote its use in scientific research and in the development of fuel, dye and other lawful industries." In spite of this, the regulations issued by the Bureau of Internal Revenue have tended somewhat to hamper the legitimate use of non-beverage alcohol. When, therefore, additional burdens are imposed upon the user and distributor of non-beverage alcohol through state legislation, the industry cannot be expected to thrive.

Such is the condition in New York State at the present time. The liquor tax law (Chap. 911, Laws of New York) imposes a tax of thirty cents upon each gallon of non-beverage alcohol manufactured or sold within the State of New York. Alcohol manufactured outside of the state is not subject to tax unless resold within the state. The result is that the legitimate consumer of non-beverage alcohol is forced to pay a premium of thirty cents a gallon unless he is in a position to buy directly from a producer outside of New York State.

Were this a new measure, we could indicate only the possible consequences. As it is, the law has been in effect since May 24, 1920, and we have only to point to the actual results. Those manufacturers who have been producing alcohol within the state have closed their plants and some of them have moved to other states. Large dealers and distributors of alcohol have refused

to do business within the state and their premises have been closed to such an extent that it is almost impossible to buy alcohol in the State of New York. Some of the larger dealers have been incorporated in other states and even though the law be repealed their business will be lost to the State of New York for many years.

Surely a little intelligent forethought would have prevented the drafting of a measure which discriminates against legitimate business interests of the state wherein the legislative body convenes. As the situation stands, it is clearly the duty of the New York Legislature to repeal or amend the offending sections of the liquor tax law.

Education by Myth And Verbal Subtleties

ONE of the most distinguished of British scientists, FREDERICK SODDY, attacked the old-time classical education in a recent number of *Nature*. He charged that the classical or arts college educates by "myth and verbal subtleties," arguing, as HUXLEY did before him, that science is slighted for "mediaeval and drawing-room studies." Continuing, he said that "the traditional education given to the ruling classes trains them to be impervious to new knowledge and able only to find in the old and dead past ideals for imitation and reverence." Science has produced most of our material wealth and has "demolished the cobwebs of traditional economics and finance," giving laws based on fundamentals and truth. According to Professor SODDY, who has had excellent opportunity to observe classical education at Oxford, where he has studied and lectured, much of the world's trouble today from war and industrial discontent is the consequence of the wrong education of the ruling class.

This is a striking indictment of classical education, all the more so because of Professor SODDY's concise way of stating it: "myths and verbal subtleties." He is objecting to the emphasis that arts colleges place upon the vast literature of old customs and traditions, upon seemingly aimless folk-lore, and upon elaborate myths such as those told by HOMER and VIRGIL. Such studies make attractive the circuitous and wasteful methods by which man has drifted from one thing to another, the inexplicable obsessions under which he has labored, the blind ignorance that has made progress so difficult and the obstinacies and loyalties that blend so curiously in human nature. Professor SODDY in speaking of verbal subtleties is objecting to the hair-splitting and the mechanical trifling that have characterized universities since their founding, and that still persist—strange mediaeval relics in our modern times.

In H. G. WELLS' "Outline of History" he points out the development of the pedant among the philosophers of the Alexandrian period, after that Egyptian city ceased to draw men like EUCLID, ARCHIMEDES and HERON. Says Mr. WELLS, speaking of Alexandria's famous museum (or university) as it existed about the time of CHRIST: "Wisdom passed away from Alexandria and left pedantry behind. For the use of books was substituted the worship of books. Very speedily the learned became a specialized queer class with unpleasant characteristics of its own. The museum had not existed for half a dozen generations before Alexandria was familiar with a new type of human being; shy, eccentric, unpractical, incapable of essentials, strangely fierce upon trivialities of literary detail, as bitterly jealous of the colleague

within as of the unlearned without, the bent scholarly man. He was as intolerant as a priest, though he had no altar; as obscurantist as a magician, though he had no cave. For him no method of copying was sufficiently tedious and no rare book sufficiently inaccessible. He was a sort of byproduct of the intellectual process of mankind. . . . We have still to discover how to preserve our centers of philosophy and research from the caking and darkening accumulations of narrow and dingy-spirited specialists. We have still to insure that a man of learning shall be none the less a man of affairs."

This habit of strange devotion to "trivialities of literary detail," as Mr. WELLS puts it, is the fault that Professor SODDY condemns as "verbal subtleties." Hair-splitting of this sort was one of the principal activities of the mediaeval universities, and undoubtedly, as Professor SODDY says, education of this kind for the ruling class of any country unfits them to appreciate the value of modern science for solving the world's problems.

However, though the arts-educated man is out of date in his thinking and painfully exasperating in his inability to understand the possibilities of the science-educated man, the lessons of the past should not be disparaged so much as Professor SODDY apparently would have us. Education by myth seems the wrong method for young men who must cope with the insistent realities of modern times, but there is much of tolerance and understanding to be gained by an acquaintance with the ancient world. When myths were the only literature of man, the human mind was being impressed in indelible ways that remain unconscious but potent factors in our nature. Habits of thinking that were formed in the childhood of the race determine our decisions today. If, as KANT said, the human mind is like a jelly-mold which transmits our experiences, much of its shaping was done in that prehistoric period when myths were current. It is not a knowledge of myths that is harmful to our ruling classes, but over-emphasis of the purely literary part of the myths and under-emphasis of the history of science in those early times. A study of the historical development of the human intelligence, with suitable stress upon the growth of knowledge in natural science, would teach a ruling class to be open to new knowledge of all kinds. The reading and discussion of man's early struggles with nature from the point of view of modern science would lead students to respect scientific enlightenment as nothing else can. The history of mediaeval times—when science was so much hindered by superstition and narrow prejudice—if taught to show how science gradually lighted the way in spite of all opposition, would induce college-trained men to give every opportunity to science as an alleviator of man's burden—which is how so distinguished a philosopher as A. J. BALFOUR regards it.

The proper combination of modern science and the old humanities in education was suggested by the late Sir WILLIAM OSLER, himself a great scientist and classicist. He pointed out that the old philosophers, who are usually studied with no idea of the growth of natural science, were themselves keenly interested in physics, chemistry, mathematics, biology, geology, etc. ARISTOTLE, for instance, was primarily a biologist; PLATO was deeply interested and impressed with geometry; the old Hindus mixed up mathematics and mysticism, but were able to grasp the idea of negative numbers before the Greeks did; such a historical personage as PYTHAGORAS was

convinced that the science of numbers explains the secrets of nature—an idea to which the atomic theory of chemistry gives some credence today.

The point then is that myths and a general classical grounding are not in themselves bad influences, as perhaps Professor SODDY's address would suggest, but that a study of the ancient world should include the history of science, and should indicate how man's blind fumbings for fundamental truths were cleared up by such scientists as DEMOCRITUS, ROGER BACON, COPERNICUS, GALILEO, DALTON, etc. The man who has been educated merely in the conventional studies of the old-time arts college is as narrow as the engineer who knows nothing of the old humanities. As Sir WILLIAM OSIER advocated, the improved education of the future should combine the old and the new, the humanities and the sciences.

Iron and Steel

Conditions in Germany

THAT the chief difficulty in the re-establishment of the German iron and steel industry is not a shortage of raw materials is made evident by the course of market prices in Germany. Scrap, which can be used very largely in lieu of iron ore or pig iron, has had a sensational decline, from a high point of 2,100 marks last March to a price of 500 marks in August, as just reported by our correspondent in Berlin. On account of the inflation in Germany and the very low rates in international exchange ordinary price comparisons are difficult, but there is a separate way to obtain information, that being to compare prices. The August price of billets is quoted at 2,365 marks, and thus we have scrap quoted at 21 per cent of the price of billets. That is an absurdly low relation, for if it obtained in the United States we should have scrap at \$8 a ton on the basis of the Steel Corporation's billet price, or at about \$12 on the basis of the billet price of the independent mills.

Making a comparison along another line, we have it that prices of semi-finished steel and finished rolled-steel products reached a high point last May and have since greatly declined, the declines running between 20 and 25 per cent. This seems to suggest that the iron- and steel-producing industry is finding itself able to function better than its customers.

Viewing the matter from still another angle, with the further decline in exchange, German iron and steel prices are attractive to outside buyers. At this writing we do not have available exchange rates between Germany and foreign countries, but a comparison by way of the New York rate will suffice. With the mark at 1.46 cents, the billet price just quoted is equal to about \$35 per gross ton, while the plate price of August is equal to 2.38c. per pound, these being far below any prices in our own domestic market, yet we have been able to do a good export trade at prices well above our domestic prices.

Thus the internal position of the German iron and steel industry is not wholly bad. There is opportunity for exports, while there seems to be more need of the domestic demand being increased than of the ability to produce being increased.

The great shortage of coal in Germany is usually stressed, and it is quite true that the shortage is acute. We are so easy-going here that we are apt to lose sight of the fact that our own conditions are very

far from reasonable. For several months past the price of Connellsville furnace coke for spot shipment has averaged eleven times its price in May, 1915, and twenty times its price in 1894. In the past fortnight there has been a tremendous decline, from \$17 to \$15 per net ton at ovens, so that the price now is only ten times the price in May, 1915. Coal has been selling at about ten times the price to which it occasionally declined at times within a few years before the war, or at twenty times the price some mines accepted in the late years of the last century. We have seemed to think nothing of this, but really Germany has no monopoly of having affairs out of joint. Germany has plenty of chances to recover, and there is no occasion to waste any sympathy. It behooves us rather to set our own house in order, welcoming all readjustments that may tend to produce a stable basis upon which we can conduct safe and sane business.

Cottonseed Investigations Urgently Required

SOME months ago certain representatives of the cottonseed industries discussed with Dr. C. L. ALSBERG of the Bureau of Chemistry the problems of steaming cottonseed. Strange as it may seem, apparently no one has ever studied the effect of time and temperature of steaming cottonseed upon the yield and quality of oil and cake obtained. The industry is beginning to realize that there may possibly be some need for sound fundamental information on this important part of the plant process. As a result of the early conferences, it was decided that a co-operative arrangement could probably be made whereby the Bureau of Chemistry would work on these problems, advising in some of the investigations which are necessary upon a semi-commercial scale. The design of cottonseed machinery is involved and the co-operation of manufacturers of this equipment was fully assured. It seemed that the problem could be undertaken at an early date and valuable results could be expected almost from the start. However, there now comes a hitch. It is the old problem of the want of a few dollars, resulting in neglect and delay of the investigation.

It seems that this industry can ill afford to permit even a month to pass without starting these studies on so promising a basis as has been proposed. Fundamental research, such as this, if guided and assisted by an experienced research organization, is almost certain to succeed. The expense would be nominal. One may properly ask why does not the industry get busy and at once provide the funds to engage a well-qualified man to take charge. If the industry as a whole cannot arrange for this work it would doubtless be profitable enough to warrant a single company in undertaking the problem.

The plant facilities required for the tests, the laboratory work for control purposes, and all the rest can easily be provided if adequate supervision is assured through the designation of the proper individual in immediate charge of the work. The industry cannot afford to let another season pass without starting these studies. The action of steam on both the cell structure of the seed and the glycerides is of the fundamental importance and is known only in a general empirical way at present. Solution of the problem will benefit the cotton planter, oil refiner and consumer.

Readers' Views and Comments

A Plea for Education of Promoters

To the Editor of Chemical & Metallurgical Engineering

SIR:—The extremely rapid development during the last few years of the industries in which chemistry plays an important part has brought into our field a type of citizen long known to us in other lines—namely, the promoter. Oil shale and platinum from “any old sands” come in for their full share of attention from this fellow, who formerly flourished in the mining game. Even the clay-working business is “honored” by his attention. I recently received an invitation to invest “with a chosen few” in a clay-working plant.

Excerpts from the prospectus as follows may be worthy of note at least from an illiterary angle:

“Are you willing to provide some of the \$200,000, or more, with others in this plant?” One is intrigued by the “or more.”

“My developments carry the saving in bad places farther than anyone else in the world, making it a safe business for Americans to go into—under my methods.” There is some satisfaction in knowing that one’s saving or savings would go far even in bad places with the methods guaranteed.

And here is another economist who settles our industrial problem, for he says: “The Government reports the immigration is landing at the rate of over 10,000 per week—this settles the whole industrial trouble—with a provision made for returning the Radicals and others.” Will Emma Goldman be here soon?

And further on he advises: “The selling to retailer is the same here as everywhere, which shows a difference of there [sic] price from my cost of over 200 per cent while these people in this country that have grown, who have the better quality, show a difference of 100 per cent to 140 per cent and they all, here, and in Germany, sell wares that have these defects and losses . . .” But why continue? If the Dorr Company or others who have equipment for clarifying sludge on a large scale want to get in touch with this chap, I will gladly furnish his address.

Mr. Editor, I call this to your attention with the thought that you may see fit through your columns to implore the more highly educated type of promoter to give some thought to the possibilities for gain in the chemically controlled industries. Do you not know a college president or two who may be interested? As long as we have “little saving to carry in bad places” we may gain much enjoyment from the post of observation.

F. GISTON.

Future Rubber Research

To the Editor of Chemical & Metallurgical Engineering

SIR:—In connection with the suggestive article on Future Rubber Research on pages 449-450 of your journal for Sept. 8, I wish to point out that although the adjectival description of the manager of the British Rubber Research Laboratory is correct, the writer has by mischance given my name instead of that of B. D. Porritt, who holds the responsible appointment in question.

D. F. TWISS.

Dunlop Rubber Co., Ltd.,
Fort Dunlop, Birmingham.

The Oil-Shale Industry and the Necessity for Common Sense

To the Editor of Chemical & Metallurgical Engineering

SIR:—The issue of CHEMICAL & METALLURGICAL ENGINEERING of September 8 contained two valuable articles, both treating upon Hydrocarbon Oils and Oil-Yielding Shales. William A. Hamor’s writings upon hydrocarbon oils are always worth reading, but at times, when he refers to the nascent oil-shale industry, he is liable to become pessimistic. Effects often follow very closely after the cause, so it may be claimed that so long as petroleum experts thus continue to “knock” the new industry, it will be found difficult to secure the funds without which a really commercial plant cannot be constructed. But despite the knocker such plants will be constructed. The plants that up to date and upon this continent have been constructed and operated do not even begin to give the industry a fair show. The industry is one that, to be operated economically, has to be operated upon a large scale, with every process well planned.

Martin J. Gavin, who wrote upon “The Necessity for Research in the Oil-Shale Industry,” has evidently lately visited Scotland and has returned so filled with Scotch methods that it would almost appear from his article that the “necessity for research” no longer existed. It is to be feared that any research undertaken by a mind so full of Scotch practice will not yield economic results. It may reasonably be advanced, from reading Mr. Gavin’s article, that his visit to Scotland has, to some extent, impaired his reasoning and observation powers. Mr. Gavin states: “The Scotch retort, when carefully examined, is found to be admirably suited for its task.” If this be so, where then is the need of research? It would be regrettable were Mr. Gavin to be taken off the research lately placed under his direction because of Mr. Gavin having already ascertained that “when carefully examined, the Scotch retort is found to be admirably suited for its task.” It may, however, reasonably be asked, What can any reasonable man expect from the operations of any machine than that it should be found to be admirably suited for its task? Fortunately for Mr. Gavin and for his research, his opinion, so given, of the Scotch retort will not be accepted as correct by those interested in the oil-shale industry.

In the consideration of this most important subject, a question that probably is the most important that will come up for solution at the hands of industrial chemists and engineers during the nineteen hundred and twenties, let common sense be exercised from the commencement.

It is admitted that the oil-shale industry has for many years been very prosperous in Scotland. It is admitted that the Scotch retort, when operating in Scotland under the local conditions there existent during the last thirty years, has given the Scotch investor satisfaction as an excellent money gainer, but is it not a matter of history that the Scotch retort and process, used in other countries, where other and dissimilar conditions existed, have proved to be a failure, in one well-known case a most disastrous failure? It is advanced

that it would have been more worth while, more sensible, to have visited the scene of that failure and to have "carefully examined" into the causes of that failure than to have visited Scotland to witness the successful operation of the retort process, *working under conditions known to be very different to those that exist on this continent*. Many years' experience in planning, construction and management of large industries has satisfied the writer that it is the failures that call for the closest examination, not the apparent successes.

Should it be impossible for Mr. Gavin to visit the works of the defunct Commonwealth Oil Shale Co. in Australia, let Mr. Gavin set down and collect all the information he can concerning the most disastrous failure of the *Scotch retort and process, operating under Scotch management, constructed under Scotch direction from Scotch plans*, and then let him reason the whys and wherefores of the failure. If Mr. Gavin will do this, he will arrive at the conclusion arrived at by the writer—viz., that there are certain serious defects in the Scotch retort and process which, although not seriously operative when working under the conditions that exist in Scotland, yet under other conditions become active and dangerous.

It is admitted that the chemical principles that underlie the method of educing the oil contents of the shale (and which are employed in Scotland for that purpose) are substantially correct. It is, however, advanced that the applications of these correct principles have been in the past and are today made most uneconomically, not only in the actual applications but also as to the operation, and that under certain conditions that are known to exist the applications are unworkable. To illustrate, the following statement shows the quantity of coal used in eight Scotch oil-shale retorting works prior to the war. These works are numbered by the writer as from 1 to 8, as the management of the several works might resent having these particulars made public were the names of the works or of the firm operating also made public. In certain cases full particulars are not available, but such particulars as are available are sufficient to prove the contention that the Scotch retort is uneconomic in its operations.

COAL CONSUMPTION PER DAY IN SCOTCH RETORT WORKS									
Works	1	2	3	4	5	6	7	8	Total
Shale daily retorted, long tons	500	500	1,000	720	1,008	850	764	590	5,932
Long tons of coal used:									
In gas producers	18.55	4.50	8.57	10.07	*	*	*	11	
Under steam boilers	66.40	30.60	57.0	*	80.0	72.0	*	*	
Total coal used	85	35	65½	*	80.0	72.0	*	*	
Tons of coal used per day for throughput of 1,000 tons shale	170	70	65½	*	80½	72½	*	*	

* The quantity of coal used was not given.

† Quantity of coal used under steam boilers only

Therefore in Scotland from 65½ up to 170 long tons of coal was used per day for each 1,000 tons of shale retorted. This, at \$10 per ton, means that these perfect retorts burned up not less than \$655 worth and up to \$1,700 worth of coal per day for each 1,000 tons of shale per day, or, reckoning 300 working days, from \$196,500 to \$510,000 per year for fuel. Most, if not all, of this fuel, if the retorts had been properly constructed or had been the wonderful machines claimed by Mr. Gavin, would not have been required. But to these very large annual totals must be added the cost of firing the coal, consisting of wages and repairs, the

total being amply sufficient to pay a large dividend upon a good capitalization.

Mr. Gavin seems to have been filled up with claims as to the superiority of the crude oil obtained from the Scotch retort. The writer has no knowledge of the oils educed from American shale, which were compared by Mr. Gavin with the Scotch crude, but he is convinced that crude oil of as good a quality can be produced on this continent without using the Scotch retort as can be produced in Scotland when using the Scotch retort. However, capitalists do not invest their money in the oil-shale business for the honor of besting old Scotch operators, but for the purpose of securing a return from their investment, and if it is found to be more profitable to produce an oil somewhat inferior in quality, it is very certain that investors will desire that quality of oil to be produced. Research work should be directed, at first, toward the economical production of such a quality of oil as is salable at the greatest profit.

It is to be deplored that Mr. Gavin should have permitted his mind to be thus influenced before he commenced upon his research work, because it will take just so much longer to convince him of the incorrectness of the Scotch claims.

The principles that underlie the eduction of oil-yielding shales are simple, though the economic application of those principles is difficult. Oil-yielding shales, broken into pieces as small as the requirements of the circulation and of the exhaustion of the educed gases will permit, are heated in a closed chamber and the gases educed are drawn off and are passed through condensers to recover the oil. The gases are then washed in scrubbers to recover the naphtha and the ammonia contents.

Temperatures that are higher than the maximum absolutely necessary for eduction *must not be used* if the maximum recovery of oil is desired, and the educed gases should not be exposed to a temperature higher than that at which they are educed.

These governing principles are very simple, but their economic application to retorts is a matter that requires much engineering knowledge and experience. This economic application is encompassed by many difficulties and too often we escape from one only to be met by another of even more importance. These difficulties are not only scientific in their character, but they are also economic, hence there should be associated with the research chemist an engineer.

The writer claims that under American conditions the Scotch retort and process are unduly costly to construct and to keep in repair, that they are immensely wasteful of heat units, that they cannot be operated without the use of large quantities of steam and that there are localities where the necessary water is not available. In such localities, were the Scotch retort to be used without steam, the resultant yield of oil would be comparatively small and the quality poor. In fact the Scotch retort is unworkable without the employment of large quantities of steam. The retort, as it is now operated, seeks to recover, in one operation, a full yield of oil and also of ammonia and it is a well-known and admitted fact that dual purpose machines are never noted for maximum yields. Maximum yields require the employment of two specially designed machines.

Let the deadly parallel speak. Let it be seen how far the Scotch retort that is claimed to be "so admirably suited for its task" conforms to the standard of perfection.

THE PARALLEL

	Standard of Perfection	Scotch Retort
Construction	Should be so designed that it is capable of being quickly constructed. The material required for construction should be readily procurable on the American continent. It should be capable of being constructed by such labor as is available at or near the locality where the retort is to be erected.	Requires very considerable time for construction. Much of the material required is special and may have to be imported, at great cost, from Europe. The labor also will, to a certain extent, have to be imported and is hard to secure even in Scotland.
Cost of Construction	Should cost <i>per ton throughput</i> as little as possible.	Exceeds many times, per ton throughput, the cost of several of other designs of retorts.
Production or Throughput	To secure economy in the cost of the construction of the retort it is imperative that the shale should not require to remain in the retort too long a time. It has been demonstrated that the oil can be educed when the shale is exposed to heat for only one hour.	Very slow throughput. The Scotch retort requires the shale to remain in the retort from twelve to eighteen hours.
Feed Into Retort	Constant	Intermittent
Discharge From Retort	Constant	Intermittent
Application of Heat	Should be arranged so that each and every particle of shale being retorted shall receive identically the like heat treatment.	Shale located next to the walls of the retort is subjected to much higher temperatures and for a much longer time than is the shale located in the center of the retort. To subject the shale in the center of the retort to the required temperatures, the shale located at the sides of the retort must be overheated and burned.
Removal of the Educated Gases	The educed gases should be removed from the retort as soon as educed and in no case should they be subjected to high temperatures.	The educed gases before removal have to be exhausted through the whole length of the retort. It is because of this that steam is required to be used so that the removal of the gases may be accelerated.
Yield of Oil	Should be the economic maximum. It is seldom commercial to secure the maximum.	Claims to recover the economic maximum, but no proofs have ever been advanced that it does so.
Quality of Oil Yield	Should be as high as possible without interference with economic results.	Claims to recover oil of high quality, but no justification has yet been advanced which warrants the presumption that oils of as high quality cannot be educed from the same shales when using other makes of retorts.
Condensation	The condensation of the gases exhausted from the retort should be so arranged that the conditions under which condensation takes place are the same during the night as they are during the day and the same during the coldest day in the winter as they are during the hottest day in the summer. In Canada the difference between minimum winter temperature (that is, more than 32 deg. F. below zero) and the maximum summer temperature (that is, over 95 deg. F.) is over 127 deg. F. While the differences of the temperature in Colorado may not be as great as that experienced in Canada, yet they are much greater than in Scotland.	In Scotland the educed gases are condensed in condensers using atmospheric air condensing. In Scotland the variation of the temperature of this atmosphere is probably within 80 deg. F. Condensers using atmospheric air condensing are also very irregular in their operations, through the constant variations in the strength, humidity and direction of the air currents. With such variation of temperature and of air currents, how is it possible to secure satisfactory condensation?

THE PARALLEL—Continued

	Standard of Perfection	Scotch Retort
Heat Conservation	Should be most carefully considered. The retort should be designed and operated so that perfect heat efficiency and heat conservation can be secured. The retort should be so operated that the forced gases produced will be sufficient to provide the heat required to heat the retorts and also required to produce the power to operate the works. The efficiency possible from the combustion of washed gases is so much higher than the possible efficiency from the combustion of coal that there is no economy in most cases in purchasing coal to use in place of fixed gases.	Heat conservation is almost entirely ignored. The losses—avoidable losses—of heat are very great. The heat efficiency of the gases burned in the combustion chambers of the retort is very low, as is also that of the coal burned under the steam boilers. All the heat contained in the educed gases is lost. As an example of wasting heat, nothing more wasteful can be instanced than the Scotch retort and process.
Area Covered by Works— Cost of Wages	It is an axiom with industrial works planners that the works shall cover as little ground as may be possible providing fire and transportation requirements are considered.	The Scotch works, etc., cover several times the ground area necessary, thereby <i>increasing the labor and overseeing</i> charges and increasing largely the cost of pipes.
Durability	The works should be so designed that the cost of repairs, and the loss of operating time consequent to such repairs, shall be reduced to a minimum.	The Scotch works are generally not good examples of works planned so as to require a minimum of repairs, but as each works would require to be criticized separately, it is not possible to particularize.
Regulation and Flexibility	The retort and other machinery should be so constructed that the application of meters, thermometers and pyrometers (plain and recording) and of pressure gages and gas recorders may be possible. Nothing should be left to the personal factor or other "rule-of-thumb" method, as is largely the case in Scotch practice. From first to last the process should be precise and yet capable of variations, as required to retort economically the variations in the quality of shale that from time to time have to be retorted.	In the Scotch retort and process the success of operations is left to the judgment of one or more men who have to rely upon their eyesight, their judgment and their experience. Such a system of operating may be possible but never desirable in locations where operations have been carried on for a long term of years, but such a system would not be economic when operating a new industry located in a new country, nor would it be possible.
Topping	Although topping is not a process that is a part of retorting, yet as topping may be a process that may be required under certain local conditions to be added to retorting, it cannot be ignored. With improved methods of retorting and condensing it is possible to make alterations in the present method and for topping that not only save expense but will produce better fuel oil and a larger yield of gasoline and kerosene.	The Scotch process is governed by their methods of condensing which prevent the employment of certain economical methods of "topping."

To illustrate the objection made to the Scotch retort because its operations are regulated by the human factor, the following anecdote current in dairy farming circles is given.

A certain dairy farm manager, who rightly had a reputation of being a good judge of milking cows (he was Scotch) resented being obliged to weigh the milk given by his herd of cows every night and every morning.

After three months' experience of the proper recording of the milk given by each cow, the expert voluntarily owned up that he had been wrong. He was frank to acknowledge that he had believed he could judge a milch cow and that he knew for certain which of his cows yielded the most milk, but that since the milk had been weighed night and morning he had found

out that certain cows he had judged to be his best were not his best and that certain other cows he had esteemed but lightly had shown up to be among his best cows. So much for the human factor. Personal observation and experience are valuable, but the results obtained by the use of the personal factor cannot be compared, for accuracy, with the results of regulation by exact measurements.

In concluding, it is to be hoped that Mr. Gavin will, at first, confine his research work to the determination of essentials and will leave the "frills" for investigation when the difficulties that concern the essentials have been elucidated. His program is a large one, so large that it is important that today's practical problems should first be investigated.

LOUIS SIMPSON.

Ottawa, Ont.

What Shall the Government Do With Its Employees' Inventions?

An Explanation by Dr. Alsberg and Dr. Cottrell of the Conditions in Government Laboratories Which Led to the Drafting of Senate Bill 3,223 Authorizing the Federal Trade Commission to License Patents Granted to Government Employees—Objections Brought Out in Open Discussion

THE following report is a selection of the salient statements made at the meeting at the Chemists' Club, New York, called on Friday evening, Oct. 15, to discuss H.R. 11,984 and S. 3,223, bills for granting the Federal Trade Commission the power to receive assignment, administer and license patents on inventions made by Government employees. The original bill has passed the Senate, and can be brought up in the House on the call for the report of the committee at any time, placed on the calendar, and acted on—passed or turned down entirely or amended; it can be amended in exactly the form it stands as having passed the Senate the second time, and then if it is passed just as it stood in the original measure, it will go to the President, having passed both houses. The Federal Trade Commission was chosen because it was felt that this body was already in a position to handle such matters, while the creation of a new agency would involve duplication of effort.

David Wesson presided and opened the meeting with one of his characteristic bearing-on-the-subject stories. He then drew an analogy between the Government and a corporation, which he noted could not handle its business like the former and survive. He continued:

"Attention has been called to two plans for improving the financial conditions of Government scientists. Perhaps we have not been correctly informed about the details of these plans, but as stockholders in our great United States Government corporation we are very much interested in them. As the matter has been put to your chairman, it would appear there is a proposal on foot to allow scientists in the employ of the Government to have the opportunity of working with the Government's resources and on the Government's time to develop inventions at the expense of the stockholders of this great corporation about which we have just been speaking. It also seems to have been understood that the Government proposes to take out and control patents for the benefit of the employees of this big corporation in which we are all stockholders. If these are the facts, they are certainly very objectionable for various reasons. In the first place, it is well established by decision and precedent under the U. S. patent law that inventions by an employee using information and facilities of the employer belong to the latter. This, of course, would put employees of our great United States corporation in a separate and privileged class.

"Again, the Government employees who are scientists would naturally have privileges which those who are not scientists cannot possess.

"There is no doubt that a law permitting individualization of Government-made inventions would make Government service very attractive and it is possible to conceive that the old saying 'a public office is a private snap' would become truer than ever."

The Problem of Dealing With Government Inventions

BY CARL L. ALSBERG

It has always seemed to me a great pity that so many of the things that are done in the Bureau of Chemistry and in the Government services generally incidental to other work lie unused in the archives of the scientific press or in Government bulletins, and I cast around for a way to make such work really useful to the people of the country. Analyzing the situation from day to day, in the course of years I began to realize that the average research man, in the Government service at any rate—it may be different in the industries—is a rather impractical sort of person.

THE OFFICE OF DEVELOPMENT WORK

It seemed to me that the only thing to do was what was being done very largely in industry, to separate to a certain extent the development and practical application from the research, and for that purpose I grouped together a few young engineers who had been in the service of the bureau for quite a while and who have made good in a great variety of ways during the war, and called them the Office of Development Work. Their job is to take anything that happens to turn up in connection with the research work or other work of the bureau that looks like a useful discovery and that might have some practical application, and in the language of our present secretary, who is an advertising man, sell it to somebody.

It is not proposed, as the press has stated, to take up anybody's invention and develop it, nor is it proposed to do any work for anybody excepting the Bureau of Chemistry's technologists, and possibly for certain other scientists in the Department of Agriculture.

SHOULD CHEMICAL WORK BE CENTRALIZED?

Now, any organization by fundamental sciences—and I take it that Dr. Wesson's suggestion that all the chemical work be grouped together in one organization is a suggestion in that direction—in the Government service, in my judgment, is just as wrong and impossible as the organization of research in a large industrial corporation by fundamental sciences. Congress does not appropriate money to advance human knowledge. If we advance human knowledge in the Government service it is incidental. Congress appropriates money for the solution of certain very definite and practical problems. It may be a problem involving the utilization of waste land, it may be a problem involving the utilization of some waste agricultural product, it may be a problem involving the prevention of disease and the improvement of the public health, but it is always a practical object, and the Congressman sees in terms of practical things.

That being so, the purpose for which money is appropriated by Congress, the objects for which we work being thus, what would happen if you grouped all the chemical work in one place? This would happen: You would expect a mining engineer to send his work, his chemical analyses, to a central laboratory. He does not know who does the work, he cannot be sure that it is going to be done by a first-class man; it might be done by a second-rater. The man who wants the chemistry of a serum studied, or the chemistry of bacteria in connection with the public health problem, has got to send his work to the same place. Fertilizer work has got to go to the same place; paper and pulp and metal and steel; and it has all got to be done without any special reference to the particular object in view.

GOVERNMENT INVENTIONS ARE INCIDENTAL TO RESEARCH

You must not go away with the idea that we people in the Government service are at work for the purpose of making inventions. Most of the work that is going on is of two types; it may be research designed to advance the enforcement of some statute, as for example the enforcement of the food and drug act—we are carrying on in the Bureau of Chemistry a great amount of work on methods of analysis of foods and drugs, in order that we may be able to detect sophistications of various kinds. At the same time our people are in constant touch with these industries; they see problems that the industry is not aware exists; they see inefficiencies and wastes that the men in the industry, because they are so close to them, do not see. They may in that way develop processes or inventions that are of benefit to the industry, incidental to their law enforcement work.

There are other inventions that are made which are purely incidental to fundamental research. A man is engaged upon some fundamental research, and incidentally, as a byproduct, develops something of use. And there are inventions that are made in connection with what I call the small industries, industries like farming, canning and making turpentine, which are small and must remain small, must be broadcast over the land; inventions which are absolutely necessary and which would be done by no other agency.

EXAMPLE OF CALCIUM ARSENATE

Take, for instance, the discovery of a new insecticide. I have in mind, for example, the use of calcium arsenate in combating the boll weevil, for it seems that thus we have a means by which the boll weevil may be kept down. Such an invention would certainly never have been made by any manufacturer. In the insecticide and fungicide industries the manufacturers have, and have always—and I can say that with some knowledge, for my father was a manufacturer of insecticides—trailed the agricultural experiment stations and the agricultural colleges.

Now, we took out some patents on calcium arsenate. We applied for a patent for every conceivable method that we could figure could be used to make calcium arsenate, and we did that very deliberately. We did not care whether a patent was granted or not, we wanted to prevent somebody else from getting it, because we did not wish to have repeated the experience with lead arsenate, which was discovered by scientists in the Government and state services as valuable for insecticidal purposes, and the manufacture of which, a rather

simple matter, was patented. We wanted to prevent some one coming along and patenting the method of making calcium arsenate, the real discovery not being how to make calcium arsenate—anybody can do that—but the discovery being that calcium arsenate is a valuable insecticide.

Most of the applications were thrown out by the Patent Office, just exactly as we anticipated, but having made the record we don't care. Actually the calcium arsenate is now being made by one of the methods that have been patented under Dr. Haywood's name, and of course everybody is using the method and nobody is paying tribute for the use of the patent.

So that, at least in the Bureau of Chemistry, is the way most of these inventions develop. There is not a deliberate attempt on the part of anybody, or has not been in the past, to invent something; but a man is engaged in some law enforcement work that deals with some industry, he sees an inefficient method or a waste in that industry—and there is an awful lot of it in the food and drug industries—and he has an idea how that inefficiency may be rectified or how that waste may be used. He does some work which leads to an invention; but he is engaged upon fundamental research, and incidentally he runs into something of value.

WHAT IS TO BE DONE WITH THESE INVENTIONS?

For example, one of the chemists in the bureau was interested in the organic chemistry of xylose, and he looked about for a convenient and cheap source of xylose. He found that he could get very easily 15 per cent of xylose calculated on the dry weight of corncobs. He made a little of it, he made the derivatives that he was interested in, and incidental to that work discovered that there were a number of useful things which you could get out of corncobs, such as 3 per cent of acetic acid and 2 per cent of furfural, and 30 or 40 per cent of an adhesive as good as many grades of dextrine. What would you have him do with it?

Explanation of the Bill

BY FREDERICK G. COTTRELL

The bill has appealed to the public very largely as a bill to provide compensation for Government employees who may take out patents. It has appealed to the public in many cases as that being its prime object. That is rather a natural way for it to appeal to the public, because the public thinks of patents in general in that personal way, of the effect on the patentee, the inventor; that is, as a means of rewarding the inventor as the sole object of the patent system. I have tried to develop, in what I have said tonight, a sense of the other point of view, that the really important thing, the thing that justifies our patent system today, is not so much the return to the inventor, no matter how laudable that is and how important that is, but the thing that affects the public as a whole with me is the efficiency that the patent system has attained in getting new things through to the general public and reaching a far larger number of people, and more effectively, more powerfully, than it possibly can the small group of inventors. In other words, from a public standpoint the patent system is justified not by what it returns to the inventor primarily, but what it does for the public in getting things through more efficiently, and representing greater progress to society as a whole.

Just so in this bill there is an element of possible reward to the inventor, but the important thing in it, to those of us who had to do with its framing and its carrying through to the present point, is in making more effective the material that is developed primarily in the Government service, in the Government laboratories, bringing that thing through to the public, so that the public at large will stand a better chance of getting material benefit in their everyday life eventually from those discoveries. Incidentally, if we can encourage the workers in the Government service to keener efforts in that regard, and give them a fairer deal in that, so much the better. But of the two points the first one is by far the more important, and I for one should be perfectly willing to see the return to the inventor entirely wiped out of that bill rather than see the other sacrificed, because there are other ways in which that can be done, through recognition in promotion, salary and so on, as it is now. I have looked upon that as a very small incidental to the whole matter.

I was not surprised that that point of view was missed, as I say, because it has been so much the habit of the public to look at the individual effect; the inventor stands up in patent work as an interesting factor, he is always a rather picturesque character which appeals to our emotional side, and is played up in every story of invention; whereas the humdrum working out of the invention in the multitudinous fields of industry and through those channels is a thing that is so generalized that it does not make very good material for the popular writer, and we are not so apt to think; we do not think in generalities quite so much. We think in personal terms much more easily.

Perhaps I might read the bill, with that much introduction, so that you will get the text of it, at this point.

The following shows the text as passed by the Senate March 22, 1920, and as amended by the Senate in Section 10 of H. R. 11,984, June 4, 1920.

Matter in brackets is matter cut out June 4; italicized matter is matter added June 4 by the Senate. When read, by ignoring bracketed matter and reading italicized matter, you have the bill as it will go to conference in December, 1920:

*Section 10—That the Federal Trade Commission be, and hereby is, authorized and empowered to accept assignment of, [or license or other rights or powers under, to develop, to issue or refuse to issue licenses under, to encourage the industrial use and application of, and otherwise administer,] on behalf of the United States under such regulations, and in such manner as the President shall prescribe, inventions, patents and patent rights which said commission deems it to the advantage of the public to be so accepted, as these may from time to time be tendered it by employees of the various departments or other establishments of the Government [or by other individuals or agencies;] and to co-operate, as necessity may arise, with scientific or other agencies of the Government in the discharge of the duties herein set out, and the Federal Trade Commission is hereby authorized and empowered to license and collect fees and royalties for licensing said inventions, patents and patent rights in such amounts and in such manner as the President shall direct, and shall deposit the same with the Treasurer of the United States; and of the total amount of such fees and royalties so deposited a certain percentum, to be determined by the President, shall be reserved, set aside, and appropriated as a special fund to be disbursed as directed by the President to remunerate inventors for such of their inventions, patents and patent rights contemplated by this section as may prove meritorious and of public benefit; *provided, that nothing herein shall be construed to give said commission or any other governmental agency any authority to engage in the manufacture of any such invention or patented article.**

The Commissioner of Patents is hereby directed to grant all patents and record all assignments and licenses contemplated by this section without the payment of any fee.

You will notice that the Federal Trade Commission is not obliged to accept all that is presented to it. It can simply choose those that are worth while. In that way it can reject and leave out those patents that it thinks can run on their own feet, the things that do not need nursing to go through into the industry.

There is nothing in the bill making it mandatory that any department or any individual shall turn these things (inventions, patents, patent rights) over.

It says various Government departments, "or by other individuals or agencies." That "other individuals or agencies" has been adopted, too, as broadening the scope beyond the Government field; the reason for that being put in in the original bill was to give an opportunity to carry out in this same way the work that is often done between Government departments and private industries, in co-operation.

LEGAL SIDE OF THE PATENT QUESTION

The clause "and to co-operate as necessity may arise with scientific or other agencies of the Government in the discharge of the duties herein set out" means simply that it is not intended that the Federal Trade Commission shall go to work and build up, within itself, a great system of scientific bureaus developing new inventions or carrying them on beyond the point. They shall administer simply the legal side of the patent question, the side of the business economics of it. In the Bureau of Mines we are interested, for example, in developing certain technical results. When we get the technical results we want that to go out into the industry. We are willing to follow the technical results and help the industry in the technical details, but we do not want to have to go out also and build up a legal bureau to study the proper relationships of these patent regulations. That is a function directly of the Federal Trade Commission, and there is where we can co-operate to a very great extent to avoid this duplication that we are speaking of.

ALL PATENT RECEIPTS TO BE POOLED

The matter of licenses, fees and royalties is a subject that cannot be worked out on the floor of the houses of Congress by general discussion; it is an economic study, it is the same sort of thing that they come to in the bureau matter, of referring that sort of study to a man who can sit down in quiet and study it as a scientific problem, and arrive at scientific methods of distribution. This is intended to indicate clearly that the return to the individual inventor is not necessarily in proportion to the amount of royalty received on that particular patent; the funds from all patent receipts are pooled, you notice. It goes into the general treasury, except for a certain percentum of the whole that is set aside for a reward. The only thing that is determined there, in the early part of the procedure, is what proportion of the total receipts from all the patents is a fair thing to be set aside as a stimulation fund for the inventors, as a recompense for this sort of work.

My own feeling is that the distribution of that particular percentum among those who receive it should be placed in the hands of an entirely separate body from the Federal Trade Commission, and should be disassociated from the body which actually does the business work.

For example, suppose somebody invents or works out and patents a therapeutic serum or other medical preparation, that from the very nature of the case is produced and sold and carried through at a minimum of cost, and reaches a comparatively small number of cases, from which the monetary reward is very small, but the saving of life and the effect on the nation is tremendously important. And alongside of that comes somebody who incidentally invents some little part of a piece of farm machinery, perhaps, in the regular course of his duties in road work or dairying or something of that kind, but that happens to be handy and convenient but of no immense significance, but happens to go into a large manufacturing field, and from the initial license happens to develop a very much larger fund than was expected from that. Fundamental justice in that thing, viewed broadly, would sanction the distribution of the reward between those two inventors, from this general pooled result, in entirely different proportions from the actual returns derived from those particular patents.

Another thing, if you pool them in that way, it takes away largely this feeling of fear that the Government employee will be apparently dominated by a commercial spirit to run after the things that are going to make money.

Discussion

Discussion was opened by R. P. Perry, who spoke in part as follows:

Dr. Cottrell and Dr. Alsberg have outlined in a very interesting way an explanation and some justification of the proposed departure.

One ostensible purpose of this departure is to aid chemical industry by Government co-operation. My own analysis is that it will do just the reverse—that is, it will hurt chemical industry by Government competition.

Our genial speakers have told us that we are mistaking their purposes and misunderstanding their aims. Perhaps so, but it is rather surprising that we who have made chemical industry our life work should not be able to understand a plain proposition even if the somewhat devious ways used in securing authority and appropriations from Congress surround the plan with considerable haze.

Disregarding the very real political difficulties which are bound to develop when the Government enters the commercial field even in a developing or advisory capacity, I make the point that the proposed departure takes the Bureau of Chemistry from its proper sphere of standardizing materials and methods of testing.

DEVELOPMENT WORK LEADS TO MANUFACTURE

The first step did not look very far reaching, but see how it led to the next. A Bureau of Chemistry employee patented a process and the bureau consented to license manufacturers to use the process, as to which license I will say a word in a few moments. They found that a laboratory process did not get very far, and so it is now proposed to have a small experimental plant and an engineering force. They will next find, as we in industry know, that small experimental plants do not go very far and they will want a larger scale operation. This will inevitably produce material in commercial quantities, and may be expected to lead to sales of the products to other Government departments, and perhaps to the public in competition with private manufacture, and the proceeds used to extend the work.

Such a development of semi-commercial or commercial manufacture may also be expected if the bureau finds, under the necessary surrounding conditions, that chemical concerns are loath or slow to co-operate on the Government terms, and the bureau may then feel itself driven to save the industry against itself by not only showing how it can be done but also doing it—at the taxpayer's expense, including of course the chemical industry's tax contribution. Mark, too, that the public notes say, naively, that "for the present the work will be confined to discoveries made in the Bureau of Chemistry." A later logical step would be to extend the work to many other lines.

It seems to me clear that by this departure the Government will lose its position of impartial judge and compete with business. Being supported by the taxpayers, it will compete on an unfair basis, and, wishing appropriations from Congress, it may be led to show or attempt to show fictitious profits.

THE CASE OF PHTHALIC ANHYDRIDE

Speaking of fictitious profits, CHEMICAL & METALLURGICAL ENGINEERING of Oct. 6 quotes from a recent address of the Secretary of Agriculture, telling of the large savings to American industry due to a single discovery in the Color Laboratory, "the catalytic oxidation of naphthalene to phthalic anhydride," which it is stated results in a saving of \$700,000 per year compared to the old German process. We in the industry have tried to figure this saving of \$700,000 per year, but cannot come within a mile of it, but that is not the whole story.

I do not wish in the least to detract from the work of Dr. Gibbs and the Color Laboratory in discovering this process, but it is not a fair statement to set out this process and the alleged saving as a justification of the proposed line of development work. It may interest some of you to know that two other parties apparently made the same discovery considerably before publication of the Bureau of Chemistry results, one a German of the Badische company and the other in our own laboratory. This important process would not have been lost to the United States if it had not been for the work of the Color Laboratory. Do not misunderstand me. I do not wish to belittle in the least their work, but I do say private industry was on the trail and found the same process about the same time.

DIFFICULTY OF LICENSING PATENTS

And this phthalic case brings up another point which shows the difficulties bound to develop when the Government tries to go into the licensing of patents. It endeavored, undoubtedly in good faith, to develop a fair license to secure the co-operation of private companies in manufacturing phthalic, and offered a form of license to us. The form which I have here is too long to analyze in detail, but it contains, among other things, a provision which requires any concern taking a license to turn back to the Department of Agriculture, and indirectly to the public, any new and patentable process developed during the course of the co-operative work. We criticised this clause as being manifestly unfair, and although two new editions of the license form have later been submitted to us this clause remains the same; and yet it appears that in one case at least the department waived this clause to another concern without notifying us of its change of base. A slip, you may say, but it is a very bad thing for the Gov-

government to slip when setting out to deal with the public on one uniform set of terms.

There are many other objections to specific features of the plan, but I have already taken more time than I would wish and will gladly leave it to others to develop the subject further. I do hope that all will grasp the significance of the proposed departure and what it will logically lead to—the Government in competition with private industry. I know industry does not want it and I do not believe the American chemists, or the American people, want it.

E. A. Sperry said: "I think that any such proposition will grow on and on in point of socialistic control, which I very much hate to see advanced in the slightest. I hope it will die in committee good and dead, I am sure."

Mr. Husted, Dr. Weston, Mr. Deppe and Dr. H. E. Howe also joined in the discussion.

REPLY BY DR. COTTRELL

In replying Dr. Cottrell said in part:

I do still feel that work of this kind has a distinctly constructive point of view, and the big things that I should hope would gradually come out of this bill—not immediately, but in the long run—would be a careful study and clarification of the whole patent administration, from a bigger and broader standpoint than perhaps it has been approached from today.

I do not feel that the knowledge or the judgment, in the application of these matters, of those who have it in charge, those who are working with the problem now, is by any means infallible. We are learning as we go along.

This whole bill was framed as carefully as we knew how to frame it, as an enabling rather than a mandatory act, so that those mistakes would correct themselves as rapidly as possible, and as much pressure could be brought from the outside in trimming up and working with that as possible. If there is any way that that can be put into safer and more guarded terms I hope you will work with us.

I am glad that one of the speakers brought out, or suggested, a point that I forgot, or at least a point that should be mentioned, as one of the dangers not only in this bill but in connection with Government work in general. That is the research bureau's tendency to work in too close to what we may call the normal advancing front of industry, a tendency that is very naturally human, to look for credit and the easiest credit, to try, sometimes unconsciously, to reach for the thing that is just going over the hill, it is just going to succeed, and grab it before it goes over and let it tow you through. That is a tendency that we have got to fight all the time, and we have got to rely on the people of bigger vision to try to inspire that sentiment in the worker.

Somebody spoke of this bill authorizing the Government employee, in getting in and co-operating with the industry, to take the results of what he found in industry and come out and patent it in the Government service. I fail to see, frankly, just how that applies to the concerns that we are working with in our Government work. We find where we have worked with them pretty closely that there is a certain large group of patents that they are quite willing to co-operate with us on. There are certain others that they do not want to co-operate with us on, and very properly so. Now this bill is not intended necessarily to apply to

every patent that is ever taken out or that might be taken out. You have got to realize that no piece of legislation of this kind is universally applicable. There is another reason why we made it simply a permissive measure; where the thing fits in and will help to forward an industry, everybody has a chance to set down and work that out. If somebody wants to co-operate with a Government agency in doing this work, in some such form as this, quite well and good. If they do not want to, there is no reason for bearing down. Yet it is the permissive feature of the legislation that I would like to emphasize. It is a question for experimental work. It gives us a chance to try the thing out and determine in actual practice what is possible.

REPLY BY DR. ALSBERG

Several important points were brought out in Dr. Alsberg's reply.

If we have some men at work on fundamental problems and if they are any good they are going to get things that will have commercial value, and you cannot stop them. What will we do with those things? Publish them? Patent them and forget them? Patent them and endeavor to have them used? And what is the machinery that should be devised to have them used?

I quite agree with those who have said that we should not turn the Government into a machine for doing industrial research, but I believe firmly that too much fundamental research cannot be done, and that there cannot be too many places in which fundamental research can be done. The industries do not do it. Tell me, how many chemical concerns in the United States have done fundamental research that has been published for the benefit of scientists generally? You can count them on the fingers of one hand. There are such places; there has been some wonderful work done in two or three; but that is all there are. The fundamental research, the research that makes new industries possible, real progress possible, is not being done in the industries themselves, and it should not be done there, as a rule. It is being done in universities, it is being done occasionally in the Government service, in this and in other countries.

FURTHER DISCUSSION BY DR. COTTRELL

In conclusion, Dr. Cottrell added a few points which he felt had not been made sufficiently clear.

It is recognized that on those things that are natural monopolies you have got to figure for control, and work it out as a public service matter. There are not a great many patents, I grant you that, that meet that condition; that need this regulation, need that application of this law. There is a great deal of material that can be handled just as we do now, by publication without patenting, or we may go a step further and use our present method of patenting and dedicating it to the public, where we know that the thing fits into industry so well, without any further or any new risk of capital, that all you need to do is to get it well on the market, and see that there is no monopoly, and everybody will go ahead and use it. But there are a great many things that need a certain degree of protection in order to carry them through the first stage, and this bill is primarily to work upon that material. Now if it is too broad, if there is danger of other things, let us try to define that and try to educate the people up in administering to that.

American Iron and Steel Institute

Account of the Eighteenth General Meeting Held Oct. 22, 1920, With a Review of the Technical Papers Presented—Blast Furnace, Basic Open Hearth, Residual Manganese, Copper Steel and Alloys for Automobile Construction Were Discussed

JUDGE GARY addressed the usual large assemblage of men interested in iron and steel, at the eighteenth General Meeting of the American Iron and Steel Institute, held in New York City, Oct. 22. The greatest part of his address covered an account of a recent trip through Belgium, France and Spain. After paying a glowing tribute to the American soldier and his effective aid in ending the war, prompted by a pilgrimage in the path of the American Army, Mr. Gary gave his impression of the industrial outlook in France and Belgium. Generally speaking, he said, the people there were extremely industrious, grimly determined and making good progress toward rehabilitation, indeed much better than one would expect, despite the fact that from one-half to two-thirds of their young men are gone, victims of German kultur.

Then passing briefly to the business outlook in America, Judge Gary said that as far as he could see there were no clouds in the sky at the present time nor were there any dangerous storms to be predicted in the near future. The decreasing volume of sales and lowering of selling price he regarded as an extremely good indication, inasmuch as nearly every line has been up to now unable to supply the demands for its product. Prices in general are outrageously high, especially as regards middlemen and some classes of employees. Mr. Gary, however, made it very plain that this statement should not apply to the wages paid to the average workman. Consequently, in his opinion, the average of the general scale of prices ought to be reduced, and the present tendency is toward a lower basis, notwithstanding the fact that every individual is willing for all others, besides himself, to make large reductions in their asking price.

RECENT DEVELOPMENTS IN THE IRON AND STEEL INDUSTRY IN INDIA

C. P. Perin discussed "Recent Developments in the Iron and Steel Industry in India." In ancient times India produced a considerable quantity of extremely high-grade iron and steel products, but until within very recent years no modern developments for commercial output of these products have been successful. About fifty years ago a steel plant was erected in Bengal, which at the present time is operated by the Bengal Iron & Steel Co. Its steel plant and rolling mill have been down for several years, but the company is making cast-iron pipe and track chairs with the product of four 80-ton blast furnaces.

About fifteen years ago some Indian capitalists headed by Mr. Tata became interested in the possibility of developing an Indian iron industry and instituted a survey to determine just what the country's resources were. Extraordinary quantities of the highest grade iron ore have since then been located. Over 20,000,000 tons of iron ore has now been located with a fair degree of probability, within an average of

about 150 miles of the coal regions. Unfortunately, however, coal has not been located in sufficient quantity to smelt nearly this amount of iron, coking coal being especially rare, only 2,000,000,000 tons of this having been found.

The coals are low in sulphur but high in phosphorus and ash, the best coals running 12 per cent of ash and this ash analyzing 1 per cent of phosphorus. At the present time, for instance, the Tata Works are using Coppe non-recovery ovens, the coke running from 17 to 20 per cent ash—a fuel which would not be looked upon with favor in America. However, a reasonable blast-furnace production is possible on account of the extremely high grade of iron ore, it containing little or no silica. The plant comprises two blast furnaces which were expected to produce 250 tons of iron per day, but actually are turning out 375 tons. The company has also constructed four 40-ton open-hearth furnaces, a combined railroad and structural mill, and several merchant bar mills. This plant was operating successfully in 1913, after several years of construction and preliminary operation.

A company called the Indian Iron & Steel Co. has two modern blast furnaces under construction. Its ore deposit contains 100,000,000 tons of 65 per cent ore. There are also two other iron companies in the formative stage at the present time. In view of the astounding reserves of excellent iron ore and cheap labor, available at from 20c. to 30c. per day, there seems little reason to doubt that within the next decade India will be able to export iron and steel products to many parts of the world.

THE BASIC OPEN-HEARTH PROCESS

"The Basic Open-Hearth Process" was discussed by F. L. Toy, superintendent of the open-hearth department of the Homestead Works, Munhall, Pa. Mr. Toy's paper was a general discussion of the furnace and its construction from an operating standpoint, and a consideration as to whether it could not be largely improved from both a mechanical and a metallurgical standpoint. It was pointed out by the author and others speaking afterward that the present construction is far from efficient; and is largely the evolution of years of experience. Changes have been slow, in a few cases the result of engineering analysis, but in the great majority of cases as a result of "cut and try," consequently the final result is due more to the operator than to the engineer.

An approximate heat balance of a modern open-hearth furnace is as follows:

	Per Cent
In the melted metal.....	14.0
In molten slag.....	3.3
Absorbed in reduction and other chemical reactions.....	2.8
Radiation loss.....	17.3
Going to the checkers.....	62.6

This gives a net over-all efficiency of slightly over

20 per cent. Of the 62.5 per cent heat going to the regenerators, 4.5 per cent is lost between the checkers and stack, while 34 per cent goes up the stack.

Efficiency in regenerators as ordinarily constructed is much lower than the thermal efficiency of blast-furnace stoves, ranging from 20 to 38 per cent. Extremely low efficiency in checker work may be expected where the furnace layout is built to fit a site rather than vice versa. Mr. Toy was understood to advocate a change in regenerator design to approximate that of a blast-furnace stove, but some of his critics took sharp issue with him, holding that the extreme high temperature and dust content of the gas entering the open-hearth checker work presented so much more severe conditions that a blast-furnace stove would need to be modified to a point where it could hardly be recognized.

RESIDUAL MANGANESE

A comprehensive discussion of the use of high-manganese iron in basic open-hearth practice was given by E. A. Wheaton, superintendent of the open-hearth department, Bethlehem Steel Co. The whole discussion revolved about the greatest problem now before the American steel maker—namely, a sufficient

TABLE I. LOSS IN SULPHUR BETWEEN BLAST FURNACE AND OPEN HEARTH

89	1.72	0.07	0.035	50
26	2.13	0.07	0.031	57

*Contains a number of high-sulphur casts. Low manganese must be held longer in the ladle to effect desulphurization.

supply of low-sulphur fuel. Mr. Wheaton's contention was that iron high in manganese could come from the blast furnace high in sulphur and yet produce open-hearth steel containing residual manganese, low sulphur and oxygen, and excellent in quality. Bethlehem Steel Co., in an effort to solve the sulphur problem, operated its No. 3 open-hearth for several months on material which must undergo the severest inspection, and records for this furnace have furnished information for Mr. Wheaton's paper.

When a blast furnace works on an ore which will furnish hot metal containing 2 per cent manganese, sulphur may run as high as 0.1 in the pig iron without danger. This means that lean slags may be run with a correspondingly low coke ratio, which in itself is a considerable advantage. High manganese causes an elimination of at least one-half such sulphur during the 80 min. the hot metal is en route from blast furnace to open hearth. Figures covering over 100 tests are accumulated in Table I.

Silicon must be low, below 1 per cent, for this elimination of sulphur, since apparently in high-silicon irons manganese sulphide reacts with $\text{FeO} \cdot \text{SiO}_2$,

If $\text{SiO}_2:\text{MnO} = 0.8$ in the mixer slag, good removal of S in the mixer will occur; in these tests it averaged 0.006 per cent.

Open-hearth operators are opposed to high-manganese charges on the ground that they decrease the tonnage of the furnace, decrease the percentage of ingot production, and badly scorify the furnace banks and the ladle linings. Experience at the Bethlehem plant seems to controvert all of these contentions. Since August, 1920, No. 3 furnace (50-ton capacity) was able to tap 70 tons of alloy ingots at an average

time of ten hours and fifteen minutes, the shortest on record. During this time the slags were notably easy to work. Ingot yields were found to be very good if no run-off slag was used. Iron oxide in the slag will average around 9 per cent with high-manganese pig and from 15 to 20 per cent with low-manganese pig. Several months' experience with this furnace shows that scorification is not severe. A bottom delay of eleven minutes per heat was recorded. As for ladle linings it was possible to get eighteen heats per ladle, using one of ninety tons capacity and teeming through a 14-in. nozzle.

In discussing the action of sulphur on finished steel Mr. Wheaton pointed out that all metallurgists agree that both sulphur and oxygen give much trouble in subsequent working, and then proceeded to argue that residual manganese reduces both of these harmful elements. A steel bath has a tendency to absorb sulphur from a furnace atmosphere in the following manner: Sulphur in the fuel is distilled as such in the gas-producer or burns to oxide. At any rate, the gas when burning in the furnace produces a considerable quantity of SO_2 , a little of which may be further oxidized to SO_3 . The latter gas coming in contact with the slag forms calcium sulphate with the free lime, and this salt later comes in immediate contact with hot iron, is reduced by the metal, and iron sulphide eventually absorbed. The reaction is

Manganese sulphide appears to be soluble both in the slag and the metal and manganese in the bath acts as a continual carrier of sulphur from metal to the atmosphere. Table II shows results from about 200 heats, and on the whole shows that final sulphur in the metal decreases as the residual manganese increases, and also that the elimination of sulphur in the practice under consideration varies directly with the

TABLE II. RELATION OF RESIDUAL MANGANESE AND SULPHUR

amount of manganese in the charge and the residual manganese in the metal.

Unfortunately we have no method of analyzing steel for oxygen, but it is generally considered that under certain circumstances iron takes up so much oxygen that the combined action of such deoxidizers as carbon, phosphorus and silicon cannot eliminate it all.

Red-shortness probably results when oxygen combined with iron is as low as 0.01, while five times as much

TABLE III. METAL AND SLAG ANALYSES FOR TYPICAL HEAT

Tests	Slag Analysis		Mn in Metal
	Fe	MnO	
1:00 p.m.	19.95	10.06	0.26
1:30	11.09	12.64	0.22
2:00	9.46	9.68	0.32
2:30 tap	9.20	9.93	0.32

makes metal unusable. Red-shortness is apparently reduced by manganese; the iron oxide is perhaps not removed, but its bad effects are certainly neutralized. A residual manganese of 0.40 has been found very effective in this respect. Table III shows metal and

slag analyses for one of Mr. Wheaton's typical heats. He holds it to be almost self-evident that a heat which for more than two hours contained an increasing quantity of manganese in the metal certainly cannot be suffering from an overdose of oxygen.

Observations of ingot from this furnace during their passage through the rolling mills showed much less tearing while blooming, and the billets required one-third less chipping for surface defects. Total yield equaled 103 per cent of comparative low-manganese rollings.

CORROSION RESISTANCE OF COPPER STEEL

D. M. Buck presented "A Review of the Development of Copper Steel," in which he cited a long list of investigations, made since 1900 both in the laboratory and under service conditions, showing that normal open-hearth steel is corroded at a much higher rate than when it contains 0.15 to 0.30 per cent pure copper.

Storey¹ investigated a large number of samples of fence wire which had been in actual service for varying lengths of time, comparing the analytical results with the history and length of life of the wires, and from this very carefully conducted piece of work states: "It has been definitely established that the durability of old steel fence wire is due to the presence of copper. Hoyt² in 1919, from an extensive series of careful experiments states: "The general conclusion which, it is believed, may be drawn from this exposure test is that the so-called copper-bearing steel, in which the copper content is about 0.20 to 0.25 per cent, offers the greatest resistance to corrosion of the common sheeting materials." The *Railway Age* for July 23, 1920, describes a series of tests conducted by the New York Central Lines on the influence of copper in the reduction of corrosion of steel tie plates. Standard steel tie plates showed approximately eight to ten times the loss as for the special copper treated ones. As a result of these experiments the New York Central has placed an order for 650,000 tie plates, or 4,000 tons, to be rolled according to the railway's standard specifications, with the addition of 0.25 per cent of copper.

The author also makes brief allusion to the results of tests by the American Society for Testing Materials.³

"At the inland industrial location, out of 146 sheets of 22-gage copper-bearing materials (0.15 per cent copper or over), forty-one sheets, or about 28 per cent, had failed after forty-one months exposure, while out of eighty-four non-copper-bearing sheets eighty-one, or 97 per cent, had failed after forty-one months exposure.

"With this overwhelming mass of evidence, we may consider it as proved that by alloying a small copper content (0.15 to 0.25 per cent) with normal open-hearth or bessemer steel the corrosion rate is enormously reduced wherever the products are exposed to alternate attack of air and moisture, which conditions prevail in practically all characters of atmosphere. It is certainly very conservative to estimate that the life of sheet metal is doubled by this treatment.

"The manufacture of copper steel has heretofore been largely confined to sheet metal, and the product has been tremendously improved. The usefulness of this discovery may readily be broadened by the use of copper in other steel and iron sections, and their life

thereby greatly increased. To mention a single example, steel freight cars, especially those of the open type, suffer greatly from corrosion. If the life of the thousands of such cars that have passed out of the field of usefulness during the past few years could have been increased only 20 to 25 per cent, the result would have gone far toward relieving the severe car shortage which has recently existed." Several hopper-bottom and gondola cars were made six years ago for the Bessemer & Lake Erie Ry., one-half the sheathing of each being ordinary plates and the other half of copper-bearing steel. Recent inspection shows much better paint adherence, and less than half the loss due to corrosion and abrasion.

"We have a simple, easily controlled, and comparatively inexpensive method of improving all of our products that are called upon to resist the attack of air and moisture, thus greatly increasing their period of service and at the same time effecting an immeasurably important step in the conservation of our natural resources."

ALLOY STEELS FOR AUTOMOBILES

Discussion of the proper heat treatment for automobile steels was presented by R. R. Abbott of the Peerless Motor Car Co., Cleveland, Ohio. In view of the fact that a great deal of research on many different lines had failed to produce an alloy steel markedly superior to any of those which have been known and manufactured for several years past, it appears that the art of manufacturing alloy steels for high strength is quite well established. On the other hand, not nearly so much is known about the correct methods of heat treatment.

Eventually, it will be possible to calculate critical temperatures, merely by knowing the chemical composition. At the present time a few laboratories do this for some of the steels which they control in great quantity and which do not vary much in percentage of the principal alloying elements.

Mr. Abbott was under the impression that no one alloy was superior to all the others now on the market. Consequently, he was of the opinion that personal preference of the user was largely responsible for his choice. Personal preference, of course, is based upon certain facts, and in this case they may be grouped together in two classes: First, the user may have been purchasing a certain brand or analysis of steel for many years and have found it to give him consistently good results, consequently he will swear by that particular alloy. Second, not all heat-treating departments are as well equipped with scientific information as they should be, and consequently they do not vary the heat treatments corresponding to different steels. Consequently one steel matches best the common heat treatments and that particular steel is the one which they like.

Future progress may be looked for by refinements in heat treating even more than in the introduction of new alloy combinations. To support this statement the author has cited the tremendous amount of research work which went on during the war to produce light armor plates of better quality than that specified during pre-war times. After doing a large amount of work on extremely complex alloys, just at the end of the war it was discovered that a very simple and old-fashioned 3½ per cent nickel steel after a suitable but simple heat treatment was far better than anything which had been produced up to that time.

An Improved Greaves-Etchells Electric Furnace Installation

A Description of the Greaves-Etchells Electric Furnace and of the Arrangement of the Electrical Equipment as Installed at the Plant of the Halcomb Steel Co.

—Records of Operation

By EDWARD T. MOORE

DURING September, 1918, the Halcomb Steel Co. placed in operation two 3-ton Greaves-Etchells electric furnaces, constructed and supplied by the Electric Furnace Construction Co., of Philadelphia, which were the first 3-ton furnaces of this type to be started up in this country.

These furnaces are used exclusively for the manufacture of alloy and high-speed steels, and therefore much attention was given to details of design, as operating conditions are much more severe in the refining of high-grade steels. In passing, it might be remarked that this company was the pioneer in the manufacture of electric furnace steels, having installed the first electric furnace in this country in 1906, this original furnace being still in daily operation.

Some years ago H. A. Greaves in collaboration with Harry Etchells realized that in the first place independent regulation of the electrodes was desirable. Secondly, that whenever a short circuit occurred on one arc of an electrode, the surge should be distributed if possible over all the primary supply phases. Thirdly, means should be taken to check short circuits and surges with-

FIG. 2 ARRANGEMENT FOR HANDLING THE ELECTRODE HOLDERS

FIG. 1. A GREAVES-ETCHELLS ELECTRIC FURNACE

out impairing the permanent power factor of the furnace by introducing extra reactance.

To fulfill the first two conditions they decided that the furnace must have a conductive hearth, but to assist in fulfilling the third requirement they decided that this hearth should have a certain degree of electrical resistance and should thus act as a resistance check on short circuits. If they could have made the ohmic value of this hearth resistance equal to that of one arc gap, all would be simple and they could have used a three-phase system with two phases applied through separate suspended upper electrodes and one phase applied to the hearth of the furnace. Such a scheme was impracticable for many reasons, but they succeeded in elaborating something which at first sight appears very similar.

In effect three transformer windings are used, the three primary windings being connected in "delta" to the three phases of primary supply.

The secondary windings are connected in "star," two legs being connected to the two upper electrodes and the third leg to the hearth. The third leg, however, which is connected to the hearth, maintains a lower voltage than either of the other two—for instance, the lower leg maintains approximately 27 volts, while each of the upper legs of the "star" transforms to 60 volts. We believe this latter voltage has been standardized at 65 volts. For refining voltage the values are 22 and 45.

FIG. 3. ARRANGEMENT FOR TILTING

The resistance between the two upper electrodes will be equal to that of two arcs, and the resistance between either upper electrode and the lower electrode will be equal to that of one arc, plus the resistance of the hearth; so that, in order that the system may be balanced, the resistance of the hearth must be equal to that of one arc to bring the total resistance to that of two arcs, and this results in nearly one-third of the energy being distributed by the hearth. Now a basic hearth is a conductor of the second class, and the resistance decreases as a function of the rise in temperature. The resistance of the bottom material near the hearth surface is made very high, but decreases rapidly toward the bottom of the lining, so that the heat generated in the hearth, through its resistance, is principally toward the top, which is in nearer contact with the steel. In proof of this theory, the temperature of the bottom of the furnace shell and the copper electrode in contact with it is such that the hand may be held comfortably in contact with them. This bottom source of heat undoubtedly assists in the circulation of the bath and accounts for the rapid deoxidation of the metal. This circulation has a still more important function in making alloy steels where rapid assimilation of the alloys and a homogeneous bath are very essential.

DESCRIPTION OF THE GREAVES-ETCHELLS FURNACE

In general, the furnace is composed of a rugged rectangular boiler plate shell of $\frac{1}{2}$ in. thickness mounted upon rockers which roll upon a toothed guide bolted to the concrete foundation (Fig. 1). Rising vertically from the furnace shell, and securely riveted at their lower ends to the shell, are four 10-in. channels. The tops of these channels are tied together with two 3-in. angle irons (Fig. 2). These channels serve as a support for two electrode holders and for two worm shafts which are used to raise and lower the electrode holders (Fig. 1). Two 2 $\frac{1}{2}$ -hp., d.c. motors, totally inclosed, furnish the motive power for raising and lowering the electrodes.

The method of tilting, Figs. 1 and 2, is by the balanced rocker type first adopted by the Electric Furnace Construction Co. for this installation, with the object of requiring a minimum effort to tilt the furnace, while the furnace remain safe in any position, accomplished by having the center of radius of the rockers

always above but very close to the center of gravity of the furnace in any position, thereby avoiding the excessive effort and heavy structure of the fulcrum type. A 5-hp., three-phase, twenty-five-cycle, 220-volt, slip ring motor situated in a pit remote from the furnace through suitable gearing and a long bronze nut operates an Acme threaded screw, which being fastened to one end of the furnace tilts it through an angle—for normal operation—of 30 deg. forward for teeming and 15 deg. backward for slagging. The tilting screw lies in an oil bath for ideal lubrication and freedom from dirt. The controller for operating the tilting motor is located on a pulpit (Fig. 3) on the melting floor. Automatic limit switches limit the travel of the furnace in both directions, but should special occasion arise, the forward tilt may be exceeded by raising the limit switch.

The electrode holders (Fig. 1) each have a carriage provided with four flanged wheels which roll on the edge of the upright channels and also four pins which slide thereon.

Electrodes of amorphous carbon 14 in. diameter are held into the holders by a series of twenty-eight copper blocks which extend around the electrode, and outside of these blocks are wrapped two thicknesses of 6 x $\frac{1}{2}$ -in. copper bus with their ends bolted to the main conducting bus. Outside the copper bus is placed a flexible supporting chain so arranged that it can be tightened by a draw bolt, thus pressing the copper bus and blocks, and clamping the electrode into position.

A new type of cooling ring has recently been added to the furnace which cools the gases escaping from the furnace between the roof ring and the electrode. The

FIG. 4. TRANSFORMER, DELTA CONNECTIONS

FIG. 5. TRANSFORMER, STAR CONNECTIONS

gases generated in an electric furnace during operation are combustible only at high temperatures and nearly all the present-day cooling rings have for their principal object the cooling of the electrode and the port holes of the roof, which means that if these gases escape to the atmosphere, they are hot enough to burn and in doing so burn up part of the electrode itself, also having a very objectionable effect on the electrode holder.

In this new cooling ring, the roof port holes are kept cool, also the electrode, and still further the gases leaving the furnace are cooled to a temperature at which they will no longer burn when they meet the oxygen of the atmosphere.

The furnace is equipped with separate teeming and slagging spouts.

LININGS OF THE FURNACE

As previously mentioned, the hearth lining is especially graded as to resistance and composed of approximately equal quantities of magnesite and "syndolag" mixed with pitch and tamped into a thickness of 22 in. at the bottom. The bottom is burned in by starting a coke fire and gradually bringing up the temperature over a period of thirty-six hours. This method produces a firm bottom, which is necessary when the hearth is used as a resistor. The brick portion of the original bottom of one furnace—that is, the brick lining immediately above the furnace shell—is still in service after having supported 1,047 heats and when the furnace was last relined with the magnesite and "syndolag" an inspection of the brick work revealed a satisfactorily working bottom.

For the very high grade of steels made we insist upon our furnace linings being in perfect condition and for this reason we have made a practice of repairing or renewing the top layers of magnesite-syndolag about once a month, which is approximately after 100 to 115 heats.

The side walls are composed of chrome brick from the hearth to well above the slag line and from this point to the roof with silica brick. The roof is also built of silica brick. In order to permit as near perfect metallurgical conditions as possible the roofs are also changed about every sixty-five heats.

As shown in Fig. 8 the electrical equipment is mounted in a separate building, but adjacent to the furnaces. The primary power used is 11 kv., three-phase, twenty-five-cycle, and is brought to the furnace substation in a No. 0000 B. & S. gage, three-conductor, paper-insulated, lead-incased cable placed in a subway. This cable is terminated in a pothead in the sub-station at a three pole double throw disconnecting switch, and then carried to a 300-amp., Type K-12 oil circuit breaker equipped with inverse time limit overload relays. From the main breaker the three conductor cable is No. 0000 B. & S. gage, varnished cambric, lead-incased and placed in a 3 in. sherardized conduit, the cable terminating at the top stud of two sets of three pole disconnecting switches mounted on the wall, 17 ft. from the floor. From each set of disconnects a No. 00 B. & S. gage, three-conductor, varnished cambric, lead-incased cable in 3 in. sherardized conduit extends to each of the furnace oil circuit breakers, 300-amp., Type K-12, equipped with inverse time limit overload relays and set to trip on 900 kw. load in fifteen seconds. From each furnace breaker a No. 2 B. & S. gage, three-conductor, varnished cambric, lead-incased cable in 3 in. sherardized conduit extends to the transformers. All cables are terminated in potheads.

Each bank of three single phase transformers is composed of two 300 kva. and one 200 kva. transformers, manufactured by the General Electric Co., and they are of the self-cooled circular coil, core type. On account of the resistive bottom serving as a current-carrying medium, which adds additional resistance in one phase, the transformer which is connected to the bottom is of smaller capacity than are those connected to the electrodes. The load in all phases on the primary side is balanced except for a short time when baking in a new bottom.

The transformers are connected in delta on the high tension side and Fig. 4 shows this connection using potheads and solderless connectors. The secondary side is "star" connected (Fig. 5) so that a load on any phase will be borne by two transformers. The units are built for 150 per cent load for one-half hour and 200 per cent load for five minutes.

The 300 kva. units have a secondary voltage of 60 for melting and 45 volts for refining and the 200 kva. units have 27 volts and 22 volts respectively; additional

FIG. 6. TRANSFORMER EQUIPPED WITH "SAFETY FIRST" HIGH-TENSION CONDUCTORS

FIG. 7. A BATTERY OF TRANSFORMERS EQUIPPED WITH "SAFETY FIRST" HIGH TENSION CONDUCTORS

full capacity taps are installed to change the above voltage values as required. This lower voltage increases the useful life of the refractories, especially of the roof, 15 to 20 per cent. The lower voltage during refining gives especially a greater length of life to the roof, since the electrodes shield a shorter arc and protect the brickwork above. Additional taps are provided so that a wide selection of voltages for melting and refining are available.

This change in voltage for melting and refining is accomplished by means of a three-pole, double-throw airbreak switch which is manually operated and interlocked with the furnace oil circuit breaker so that it is impossible to move the tap switch without first opening the oil breaker.

The main high tension conductors to the transformers

FIG. 8. SWITCHBOARD

are brought to the transformer bushings through No. 2 B. & S. gage, two-conductor, varnished cambric, lead-incased cable in 3 in. sherardized conduit and terminated in two conductor potheads opposite the transformer bushings. (Fig. 6). The tap connections are brought to the transformer bushings through No. 2 B. & S. gage, three-conductor, varnished cambric, lead-incased cable in 3 in. sherardized conduit and terminated in three conductor potheads opposite the transformer bushings. (Fig. 6). The two conductor potheads carrying the

main leads are placed over the three conductor potheads carrying the tap connections in order to avoid placing the riser conduits side by side, as by the method used it is possible to remove any transformer from the bank without disturbing the others, which would not be possible were the other method used. The leads from the transformers are connected to the cable conductors by solderless connectors which have proved very satisfactory for this class of construction. The exposed conductors between pothead bushings and transformer bushings are insulated with varnished cambric to withstand five times normal voltage, or 55 kv. By this arrangement of connectors a transformer may be disconnected from the system in a few moments.

All high-tension conductors were manufactured under

FIG. 9. METER WIRING

specifications made by the Halcomb Steel Co. and are lead incased and all terminate in potheads, the only exposed cable being at points where the conductors pass into the transformer bushings, the oil breaker bushings, the tap switch lugs, and the delta connection. In these instances the conductors are insulated with varnished cambric tape to a thickness to withstand five times normal voltage, or 55 kv., then painted with compound to render them non-absorptive.

This method of construction (Figs. 6 and 7), which may be called a "Safety First" installation, is the only one of its kind, so far as we are aware, in existence, and letters patent are being applied for, covering this method of construction. With the present types of exposed high-tension wiring in use much trouble has been experienced from flash overs on insulators due to dust, and many accidents, some fatal, from men coming into contact with the high-tension equipment while

FIG. 10. GRAPHIC RECORD OF KILOWATT VARIATION DURING A HEAT

about their duties. With this improved method it is possible to climb all over the equipment without danger and since its installation it has not cost a single cent for maintenance or repairs. This "Safety First" type of construction will increase the cost of the electrical wiring system about 60 per cent over the regular open wiring method, and for a 3-ton installation this amounted to \$2,200 in 1918.

From the secondary coils of the transformers, copper busbars extend in interlaced formation to the wall which separates the transformers from the furnaces. In an opening in this wall the "star" connection is formed (see Fig. 5), and outside the wall on the furnace side the current transformers are mounted, and

thereby recording the time a circuit breaker is opened or closed and the duration of time in each position. From the chart on this meter it is a simple matter to count the number of times the breaker is operated, which serves as a guide for determining when to change the oil in the breaker tank. The potential and current transformers on the primary side are mounted on a pipe frame behind the switchboard but a sufficient distance away to prevent any trouble being communicated to the wiring on the back of the switchboard. All meter wiring (Fig. 9) is of fire-proof insulation and is suitably terminated on terminal blocks so that tests can be made without cutting or opening a circuit.

The auxiliary hand control panels for operating the

FIG. 11. GRAPHIC RECORD OF POWER FACTOR VARIATION ON THE HIGH-TENSION SIDE OF THE TRANSFORMERS DURING A HEAT

the flexible cables, which loop to the furnace in phase groups, are attached to the ends of the bus just outside the "star" connection. These cables, of which there are twelve for the center phase and eight for the outside phases, are 600,000 circular mils and composed of sixty-one strands—seven wires to the strand and rope laid. The groups of cables forming a phase are supported on wooden grooved drums so as to take away all strain and weight from the cable lugs.

The switchboard (Fig. 8) contains an indicating wattmeter, watthour meter, low tension voltmeter with voltmeter receptacle and plug, two ammeters, inverse time limit overload relay, contactors, contact-making ammeters, oil breaker operating mechanism and tap switch operating wheel. A General Electric automatic regulator controls the position of the electrodes, and consequently the power input of the furnace. A graphic polyphase wattmeter and graphic polyphase power factor meter are installed in the substation. A recording thermometer is also installed having two pen movements—one to record the room temperature, the other to record the oil temperature in the transformers. The oil breaker operating handle is connected to a signal switch which lights a red or green signal lamp to indicate visually the position of the breaker. The signal switch also has a separate contact for connection to a recording meter having pens which move laterally,

electrode motors by hand are shown in Fig. 8 at extreme left and right of cut. Current for electrode motors is furnished by a 20-kw., 230-volt, d.c. compound wound motor generator set located in the substation.

Low secondary voltage used during refining. Highest current values: No. 5, 25.8; No. 4, 14.5; No. 6, 16.9.

wattmeter recording the kilowatt variation during one of the heats. The melting period started at 1:38 p.m., and by 2:25 p.m. a considerable pool of molten metal was formed. At 3:48 p.m. the metal was all melted and the voltage was reduced to the low refining voltage with an input of approximately 575 kva. At 4 p.m., the load input was reduced to 300 kva. and at 4:08 p.m. was further reduced to 230 kva., where it remained until the end of the heat at 5:22 p.m., a total length of three hours forty-five minutes. The exceptionally low input required to maintain the heat balance during the refining period is worthy of note, and this low input can be obtained only by using a low voltage relatively during refining. The advantage of the use of a lower voltage for refining than for melting was first discovered and used in this country by the Halcomb Steel Co., and patents were applied for some time ago covering the process and apparatus in connection therewith. Fig. 11 is power factor chart for above heat, and represents the operating power factor on the high-tension side of the transformers.

Electrode consumption over a considerable period was 30.6 lb. per net ton of steel produced, including electrode breakage. Due to "war quality" electrodes, this figure is somewhat higher than during normal times, as a consumption of less than 20 lb. per net ton, including breakage, has been secured over many monthly periods.

The temperature of the transformers during a day's run varied quite gradually from 32 deg. C. at 9:30 a.m. to 50 deg. C. at 7:30 a.m., the ambient or room temperature varying during the same period between 12 and 20 deg. C. The time between heats of the charging period causes a small reduction in temperature. The room temperature was only 4 to 5 deg. higher than the outside air and demonstrates the efficiency of the ventilating system used in the substation.

In order to determine the maximum overload currents which could be drawn by the furnace, instruments were connected into the circuit with instrument transformers as per Fig. 12. The numbers used in the following data refer to the corresponding numbers in Fig. 12.

Primary volts, 11,300--11,500.				Secondary volts, 59--61--81.				
Meter	No. 1	No. 2	No. 3	No. 4	No. 5	No. 6	No. 7	No. 8
Starting heat	35.2	24.0	51.2	6.4	31.2	22.8	7,000	2,000
1 hr. after start	48.0	36.8	27.2	16.0	27.6	25.2	4,600	5,750
2 hr. after start	33.6	33.6	35.2	14.4	21.4	22.8	5,000	6,500
	36.8	32.0	37.6	14.4	27.0	22.2		

There were swings as follows:

0 84.0 84.0

This indicates clearly the bottom of the furnace has a very high resistance when cold, although this does not prevent an adequate current flowing for rapidly baking in a new bottom.

FIGS. 19 TO 21. OSCILLOGRAPH TESTS OF GREAVES-ETCHELLS ELECTRIC FURNACE NO. 6 AT THE HALCOMB STEEL CO. PLANT

Fig. 19. Current and secondary voltage waves in furnace No. 6. Hand control. Start of heat. High secondary voltage. Amm. No. 5, 51.4 effective amperes. Current and secondary voltage waves in furnace No. 6. Automatic control-refining. Amm. No. 5, 19.9 effective amperes. Voltage on Nos. 2 and 3, 60 volts, read on portable meter. Vib. No. 2, volts west electrode to bottom. Vib. No. 3, volts east electrode to bottom. Dec. 31, 1918. Fig. 21. Secondary voltage waves in furnace No. 6. Automatic control. 400 kw. in furnace. Vib. No. 1, volts west electrode to bottom. Vib. No. 2, volts west electrode to east electrode. Vib. No. 3, east electrode to bottom. Dec. 31, 1918.

Referring to the oscillograms, the following table indicates the effective values of the maximum currents observed:

Fig.	300 k. P.F.	200 k. P.F.	300 k. P.F.	
13	96.8	43.7	87.9	Hand control. Electrodes purposely shorted.
14	29.5	26.2	35.4	Hand control. Start melting period.
15	75.4	70.8	54.5	Hand control. 1 to 1½ hr. after start of heat.
16	94.6	36.6	60.5	Hand control. 1 to 1½ hr. after start of heat.
17	52.3	37.3	73.6	Automatic control. High secondary voltage used during melting.
18	25.3	14.5	16.9	Automatic control. Low secondary voltage used during refining.
19	Eff Amp 51.4	Volts 60.0*	Volts 60.0*	High control. Start of heat. High secondary voltage.
20	19.9	60.0*	60.0*	Automatic control. Low voltage. refining period.
21	Volts west electrode to center	Volts east electrode to center	Volts east electrode to center	Automatic control. 400 kw. in furnace. Low voltage. refining period.

* Voltage on 2 and 3, east electrode to read on portable meter

By referring to the oscillograph curves it will be noted that during the melting period the load is constantly changing from zero to three to four times normal. The frequency of these surges is such that a very few seconds may exist between them, although with a properly designed installation they are not severe enough to make this class of load undesirable to the central station—in fact, a furnace load is a very desirable one due to its 24-hr. use. With several furnaces operating on a system the diversity is such that only occasionally are demands excessive. There is also some variation in the severity of the load with different furnace charges. In other words, the position and shape of the scrap metal which is next to the electrodes when starting the heat is such that occasionally the initial melting of the charge is more severe than at other times.

These tests indicate that electric furnace loads are more severe on transformers than are the usual lighting and power loads, first, because breaking the low voltage arc on the cold metal may, with the proper combination of conditions, set up oscillations in the transformers, and second, because subjecting transformers to a severe short-circuit occasionally is a very different matter from subjecting it to hundreds of partial short-circuits per hour. It is for these reasons that furnace transformers should be especially designed to withstand the tremendous mechanical stresses produced.

Figs. 19 and 21 show evidences of high frequency, although not especially high, being between 6,000 and 9,000 cycles.

The current records in Fig. 17 are not symmetrical, which would indicate a partial rectification.

The maximum current values found in the oscillograph tests are not as high as those found in the meter test. This is because it was possible to observe the meter over a longer period of time and thus determine the maximum of many current rushes. The oscillograph measured the maximum current for the particular current rush for which the film was taken, but the one just before or after might have been higher. It would be very desirable if a very long film holder could be devised so that a reasonably long record could be obtained—long enough to cover any reasonable observable period—as under operating conditions it is very difficult to determine just when the looked-for phenomenon is to occur.

The phenomena of high frequency and rectified currents are not peculiar to this type of electric furnace, as similar results have been secured during oscillograph tests made on other makes of furnace—in fact, the electric arc itself is responsible for whatever current rectification takes place.

Our experience has been that an electric furnace installation when properly designed and constructed is a desirable load for a central station and with this type of furnace the fluctuations seem to be such that it has proved itself to be an attractive proposition to us as steel makers and also to the central station supplying us with power.

Syracuse, N. Y.

Who Is Your Boss?

You're working day after day in the big shop.

You're getting a certain amount of money for your work.

You're either satisfied and happy or else you're sore about something.

If you're satisfied and know you're getting along all right—fine!

If you're sore, I want to ask you one question.

Do you know who is your boss?

"Sure, Mike," you say, "I'm working for the man who owns this business. He's my boss!"

But that's not so—not on your life!

You're working for yourself.

You betcha are!

Sounds funny, don't it?

It's a fact just as sure as you're a day old!

You're in business for yourself just as much as the big guy who owns the business.

The big guy isn't your boss at all.

He's your customer, and you're selling something to him, just like he's selling something to the people.

The only difference is that he's got a lot of money tied up in the business which he takes a chance on losing.

You've got your money in the savings bank where it's safe.

Now, the "boss," he's selling goods to his customers, the people—because the people need them.

And you're selling your work to your customer, the "boss"—because he needs it.

Now, supposing the "boss" starts in to make poor goods. He don't give the people full value for their money.

What happens?

Why, the people find it out and won't buy his goods. They buy some other guy's goods and he loses his customers.

Now, supposing you start in selling your customer, the "boss," poor work. You don't give him a full day's work for a full day's pay—what then?

Why, the boss is going to do the same thing with your poor work that the people would do with his poor goods.

He's going to buy someone else's work. You lose your customer and have to look for somebody else to sell your work to.

The people have got a right to buy the best goods they can get for their money.

The "boss" has got the right to buy the best work he can get for his money.

You've got to look at it this way before you can get ahead.

—Arizona Mining Journal, October, 1920.

Precautions in the Use of Dimethylsulphate

BY MAX MUELLER, PH.D.

ALTHOUGH dimethylsulphate is known to be the most convenient methylating agent and is used in large quantities in Europe in both the dyestuff and the synthetic perfume industries, it has not yet met in this country with the attention it deserves. This is due principally to the widespread opinion that it is an extremely dangerous poison. Text books have exaggerated its poisonous effects when many things more dangerous—things in common use—are not so mentioned. The danger with it is not greater than, for example, with aniline, provided the proper precautions are taken.

The reasons why dimethylsulphate should be preferred to other methylating agents are first, because it acts at low temperatures; second, the methylation can be conducted at atmospheric pressure. The following reactions show the mechanics of the methylation of phenols:

Reaction (1) is complete at ordinary temperature; reaction (2) generally requires 100 deg. C.

The reaction with amines is more complicated since, as is the case with all methylating agents, all the possible methylated products may be formed.

R-NH_2 may give R-NHCH_3 ,

By choosing the right conditions, however, the desired compound can be obtained in good yield.¹ As a rule the methylation is carried out by adding simultaneously dimethylsulphate and alkali to an aqueous solution or suspension of the phenol or the amine. Sometimes the results are better when dimethylsulphate is added first and then the alkali. The temperature varies from 0 to 30 deg. C. Also benzene, ether or dimethylsulphate itself are used as diluents in some cases.

Commercial dimethylsulphate is almost chemically pure. It is a colorless or faintly yellow liquid of sp.gr. 1.334 at 15 deg. C. It boils at 188 deg. C. It has rather a pleasant etherial odor. It does not contain free acid and does not attack metals, and so may be kept in iron drums or containers.

Some danger thus lies in the harmless appearance of this compound. Moreover, the danger is increased by the fact that it has a considerable vapor pressure in spite of its high boiling point, and that its action on the skin and mucous membrane is not immediate. The vapors attack the delicate membrane of the eyes and respiratory organs, while the liquid is readily absorbed by the skin and then acts internally. Its poisonous action is a combination of the actions of its decomposition products when it reacts with water.

The action of the methylsulphuric acid is local. It blisters the skin and forms sores which take a long time

to heal. The action of the methanol is general, affecting the central nervous system and in some serious cases a weakening of the optic nerve was observed.

As pointed out by Weber² some men died by its action in the early days of its use, but during the last ten years no fatal accidents have been recorded. During the writer's twenty years experience in handling dimethylsulphate only very few serious cases occurred and these during the earlier years. Most of these were due to the carelessness of the workmen.

Its action thus being known, the following precautions should be observed:

All containers of dimethylsulphate should be kept out of doors, but in a dry, cool place. Small bottles for laboratory use should be kept in a separate room with other dangerous chemicals. Storage tanks for the plant should be installed in sheds outside the methylation building. The reaction tank should have a tight cover and a ventilating pipe leading through the roof, equipped with a steam injector so that a slight vacuum is formed in the pipe and any dimethylsulphate vapor escaping is destroyed. All transferring of dimethylsulphate from one tank to another should be done by vacuum.

It is not as easy to destroy dimethylsulphate as one would think from its reaction energy. It is slightly soluble in water and is not instantly decomposed even in presence of an excess of alkali. The decomposition is rapid only at about 80 deg. C., but proceeds then with such a production of heat and so quickly that if any considerable amount of dimethylsulphate is present, vapor produced will project the whole contents of the tank through the openings. So if apparatus containing dimethylsulphate has to be cleaned, the greatest amount of it has to be removed. What remains is destroyed by adding enough diluted caustic soda for neutralization and passing a current of steam through the whole apparatus until its temperature is higher than 80 deg. C.

Any amount of dimethylsulphate dropped on the floor should be covered immediately with dry soda ash or caustic lime and then washed away with water after a few minutes. If working in an atmosphere of dimethylsulphate is necessary, a tight army gas mask should be worn. It proves to be efficient for fifteen minutes at least.

The treatment of men gased by dimethylsulphate depends on the gravity of the case. If the eyes are attacked, they should be washed two or three times with caron oil. This treatment is somewhat painful, but if done in time prevents all serious trouble and generally allows the man to go back to work the following day.

In more serious cases dimethylsulphate vapors may get into the respiratory organs, provoking an inflammation of the larynx and bronchial tubes. In this case it is best to send the man to the hospital or at least to keep him under close observation, as sometimes breathing may become difficult for a few hours and the administration of oxygen may become necessary.

Clothes impregnated with dimethylsulphate must be removed immediately and washed with boiling water and soda ash.

With the ordinary precautions of cleanliness and care that should be exercised with any organic chemical, no serious consequences will ever result and the writer wishes to impress upon the profession to set aside the previous exaggerated conception of the danger of this product.

Legal Notes

BY WELLINGTON GUSTIN

Widow May Not Recover Where Employee Assumed Risk of His Employment

In an action under the common law for damages for death of an employee the Court of Appeals of Georgia has dismissed the case brought against the Donalsonville Oil Mill by the decedent's widow. It was alleged that the negligence of the defendant corporation consisted in not furnishing the deceased a safe place in which to work. It was shown that complainant's husband had at least equal means with the Oil Mill company of knowing that the place in which he worked was unsafe and that he voluntarily continued, and without objection, in the employer's service. Therefore, said the Court of Appeals, it was not error to dismiss complainant's petition, it showing there is no right of action accruing, and judgment was affirmed.

Meaning of c.i.f. as Distinguished From f.o.b.—Rules Governing Such Contracts of Shipment

Some interesting propositions of law arise in the case of Fred O. Seaver against the Lindsay Light Co. decided for the plaintiff by the Supreme Court for Kings County, New York.

A broker in London asked the defendant in Chicago if it had thorium for sale. The broker was referred to defendant's brokers in London, who would quote prices. After various correspondence between the two brokers, defendant's broker submitted an offer from the defendant. This was accepted in a cable sent the defendant at Chicago, and the defendant's confirmation of this acceptance was contained in a cablegram sent to its London agents and transmitted by them to the first broker. The acceptance of the final offer showed that the goods were being purchased for a corporation in Holland. The thorium was to be delivered in six monthly installments at the price of \$4 a lb. cash in advance, c.i.f. Rotterdam. Later, by mutual consent, the contract was changed to c.i.f. London dock. A portion of the monthly deliveries was never shipped, and this action was brought to recover the damages sustained by the buyer, the plaintiff being its assignee.

PLACE OF DELIVERY THE IMPORTANT FACTOR

The buyer claimed the contract was made in London, the seller claimed it was made in Chicago. The court thought the latter contention correct, but held this was immaterial, for in an action between buyer and seller for damages for non-performance of a contract of sale the place of delivery is the important factor. The damages are measured by the value of the goods at the place of delivery, and not at the place where the contract was made.

The question as to what was the place for delivery under this contract is to be determined according to the intention of the parties.

Ordinarily, in the absence of special facts, a contract to sell goods is completed when the seller delivers them to a carrier to be transported to the buyer. That constitutes a delivery to the buyer, and this is true although the goods are not then paid for.

But this rule does not apply, said the court, if the seller agrees to deliver the goods at the buyer's place, or makes some other agreement showing a different intention of the parties. So, under the common provision f.o.b. place of shipment, the seller's obligation is completed when he ships the goods, and title to them passes then, and he is not obliged to pay the freight. But if the agreement is f.o.b. place of destination, the seller must pay the freight, and may be deemed to have retained the title to the goods until their arrival at the point of destination. But where the intention of the parties is different that will control. Hence the fact that the freight was paid by the seller is not conclusive that the delivery was to be at the place of destination.

MEANING OF THE TERM C.I.F.

The provision c.i.f. seems rarely to have been used in commercial contracts in this country, and many textbooks contain no mention of the term. It is defined in II Corpus Juris, p. 765, as an expression indicating that the price fixed covers the cost of the goods and insurance and freight on them to the place of destination. Under a contract containing such a provision, the seller must ship the goods, arrange the contract of affreightment to place of destination, and pay its cost or allow it from the purchase price, and procure insurance for the buyer's benefit for the safe arrival of the goods and pay therefor. When the seller has done this and forwarded the papers to the buyer, he has fulfilled his contract, and delivery is complete. There is no obligation by the seller to deliver the goods at the place of destination.

The above principle was stated and approved by the Supreme Court of the United States in *Thames & Mersey Insurance Co. vs. United States*, 35 Sup. Ct., 496. This is the meaning and effect of the letters c.i.f., in the absence of any agreement to the contrary or any provisions showing a different intention. The court was convinced no different intention was shown in the cause on trial, and this was emphasized by the requirement that the seller must procure insurance for the buyer's benefit. This indicates, said the court, that delivery was to be complete at the place of shipment and that the title to the goods was in the buyer from that time. Hence the buyer required the seller to secure insurance for him. If the goods were still the seller's until they reached their destination, the risk of their safe arrival would be the seller's and the buyer would have no concern about that. He would lose nothing if the goods did not arrive; the loss would fall upon the seller. This and similar provisions in contracts have been held to be controlling factors in determining the intention of the parties.

If it had been the intention of the parties that delivery should not be complete until the goods arrived at London, an "f.o.b. London" provision could have been inserted in the contract. The difference between an "f.o.b. London" contract and a "c.i.f. London" contract has been pointed out.

So there is nothing here to show the parties had in contemplation that the value of thorium in London should be the measure of damages. The buyer proved the value of thorium in London, but offered no proof as to its value in Chicago. The seller's proof of the Chicago value plus freight and insurance charges was therefore undisputed, and must be accepted as the basis upon which the buyer's damages must be calculated. The same rule of damages applies where there is no shipment made as where a shipment is made that does not conform to the contract.

Industrial Excursions of the Chicago Meeting of the American Chemical Society

Notes on and Views of the Doehler, Sherwin-Williams, Pullman, Fleischmann, Steel and Tube, Northwestern Terra Cotta, Fansteel, Sears-Roebuck and Heath & Milligan Plants

WEDNESDAY afternoon and all day Friday, Sept. 8 and 10, of the program of the Chicago meeting of the American Chemical Society were given over to industrial excursions. The following notes and views are offered both by way of report of the meeting and as a record for future reference of the important plants operating in this district.

DOEHLER DIE CASTING CO.

While this plant is a small one as compared to some of those visited, it is nevertheless important from the point of view of uses of alloys in the construction of machine parts. These alloys are made up with a zinc base, a tin base, a lead base, an aluminum base and a copper base. They are melted in the foundry, a corner of which is shown in Fig. 1, and cast in ingots for subsequent use in the die-casting machine. It is not economical to make a die casting where less than 5,000 pieces are required, as the dies are extremely expensive to make.

At the Chicago plant gas is used for fuel and requires from $1\frac{1}{2}$ to 4 cu.ft. per lb. of metal produced, the higher figure being required in the making of an aluminum alloy. A large quantity of compressed air is used in the operation of the die-casting machines and is supplied from one Ingersoll-Rand and two Sturtevant air compressors at a pressure of about 200 lb. per sq.in. The casting operations are extremely interesting from a mechanical point of view. As the pieces come from the machine they are cleaned, hand filed and often trimmed in dies.

Tin-base alloys are not attacked by organic acids and can therefore be used for food containers. They are slowly corroded by mineral acids and alkalis but are comparatively unaffected by water, neutral aqueous solutions, and damp or warm climatic conditions.

Lead-base alloys are insoluble in dilute sulphuric acids and are consequently well adapted for fire extinguishers, etc. They are soluble in nitric acid, but very slowly soluble in hydrochloric acid. Contact with organic acids form the base of lead salts which are poisonous.

Aluminum-base alloys are readily soluble in alkali solutions, but insoluble in nitric acid. They are also readily soluble in dilute hydrochloric and sulphuric acids, and soluble with difficulty in these acids when concentrated.

SHERWIN-WILLIAMS CO.

This plant is one of the largest manufacturers of insecticides, paint and varnish and the raw materials for these products in the world. It also manufactures lithopone pigments, tin cans, dyes, dry colors, wood preservatives, tar products, and makes the largest amount of acetic acid for its own consumption of any plant in the world. The old Dutch process white lead

plant, which was visited by the members of the society, will be described in a subsequent issue.

The company is just erecting a new quick-process white lead plant which will increase the capacity for white lead production 15,000 tons per year. This new plant under construction is shown in Fig. 2. At the same time the company is erecting a plant for the manufacture of red lead and litharge.

THE PULLMAN CO.

From the point of view of large-scale manufacturers the Pullman Co. was one of the more interesting plants visited. The underframe of the Pullman car is first erected on temporary trucks, the end frames are then set on and the next shop puts on the sides and roof. When all the heavy steel work is erected the permanent trucks are substituted for the temporary trucks and the car goes to the yards for a sand blasting. A priming coat is put on over the outside and finally the finishing coat.

The first work done on the interior is the construction of a "chanarc" steel floor over which a cement floor is laid. This cement consists of magnesium oxychloride. The interior finish of the car requires the work of many craftsmen, including woodworkers, electricians, plumbers, interior decorators, etc. The completed car costs between \$20,000 and \$50,000.

The shops cover space $\frac{1}{2}$ mile wide and $1\frac{1}{2}$ miles long and employ 9,000 to 13,000 men in the operation. The capacity of the plant is two Pullman cars and four coaches per day. These coaches, together with the freight cars, are made in a separate shop.

The company is just putting into operation a new freight-car shop which will produce a completed freight car every fifteen minutes, the assembly being carried on after the manner in which Ford automobiles are assembled.

The work in the chemical laboratory consists mainly in supplementing the work of the Committee of Standards and analyzing material for the purchasing department.

The company is also engaged in the manufacture of automobile bodies.

FLEISCHMANN CO.

This plant manufactures cider vinegar, malt vinegar, white wine vinegar and yeast. The most interesting process inspected by the members of the society was the manufacture of yeast.

This is made from a mixture of corn, rye and barley malt. The grain, on arriving at the factory, is first subjected to a cleansing process by which all dust and any foreign substances are removed. Grains are subsequently ground separately in regular milling machines of the same type as those used for grinding wheat in the manufacture of flour.

FIG. 1. Cupolas in Doehler foundry.
 FIG. 3. Erecting shop of the Pullman Co.
 FIG. 5. Centrifugal yeast separators.

FIGS. 1 TO 6

FIG. 2. Sherwin-Williams plant.
 FIG. 4. Machine shop of the Pullman
 FIG. 6. Yeast presses.

The preparation of the mash consists of setting the ground grains to soak in filtered water. This has the effect of softening the starch, and in order that the final solution may contain all the elements for nourishing the yeast cells, the different grains are treated in distinct ways. For example, the corn is mashed at a high temperature, the rye being put into the mash after the corn is cooked. Malt at a lower temperature is added to convert the starch of the corn and rye into sugar. This is accomplished by the diastatic power of malt. The mash itself is sweet and contains no alcohol.

The next step is the addition of lactic acid bacteria. During this process the temperature is carefully regulated and within sixteen hours the lactic bacteria have multiplied to such an extent that the mash has a distinctly sour taste.

Upon completion of the lactic process the mash is run into filter tubs having perforated bottoms. The solid

particles of the grain are held back and a perfectly clear extract known as wort is obtained by the filtration. This is then heated to a high temperature to remove other bacteria besides the lactic ferment. The wort is then conducted through pipes into huge copper tanks (fermenters). In these tanks specially prepared pure culture yeast is introduced. Compressed air is forced in, the oxygen in the air aiding the growth and reproduction of the yeast cells from the mother or culture yeast first introduced. During this process the temperature of the wort is carefully controlled by a system of cold-water coils in the fermenters; the yeast cells under proper conditions of temperature and aëration multiply very rapidly and in about twelve hours a large amount of yeast substance is formed.

The yeast substance is then separated from the liquid by means of centrifugal separators shown in Fig. 5 in the same manner that cream is divided from milk.

The yeast leaves these separators in fluid form like heavy cream and is conveyed by pumps through a cooling apparatus into a receiving tank and from there into a series of filter presses. Here the superfluous water is squeezed out and compressed yeast remains in the

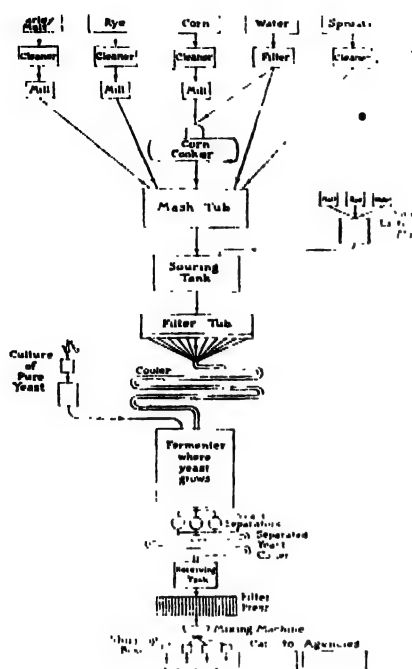

FIG. 7. DIAGRAM OF YEAST MANUFACTURE

presses. After removal from the presses the yeast is thoroughly mixed by machinery, packed by hydraulic pressure in 80-lb. boxes, and placed in a large refrigerator. A flow-sheet of the complete operation of the plant is shown in Fig. 7.

STEEL & TUBE CO. OF AMERICA

This plant is one of the most modern in type of equipment of any in the United States. It has every known labor-saving and safety device for increasing the output and protecting the workers. About 2,000 men are employed at the present time and the output is between 1,500 and 2,000 tons of steel per day.

Ore is unloaded from the steamers from the Lake Superior regions by cranes at a point where it can be easily transferred to the blast furnaces. Approximately 100 tons of coal is used at the plant every hour in the coking operation. Between 15,000,000 and 16,000,000 cu.ft. of gas is made every day. This gas is consumed in the steel plant.

A bessemer plant is now under construction as an addition to these works. Improvements will include a cupola, mixer and converter building, bottom house, office building, power plant and boiler houses. The cupola building will contain three cupolas each having a capacity of 40 tons per hour. This is quite an addition to the colonies of steel mills on the lake shore in the Chicago district.

One of the features of operation of this plant is the new town which is being built to house employees. About 200 houses have been built, together with a boarding house containing fifty rooms. The town is complete in every respect, containing garages, stores, sewage and water systems with capacity to supply the town. The houses are of masonry construction with hollow-tile walls, stucco on the outside.

THE NORTHWESTERN TERRA COTTA CO.

In addition to the brief outline given on page 370 of *CHEMICAL & METALLURGICAL ENGINEERING*, vol. 23, No. 9, the most recent development of this large ceramic ware plant is the addition of the new 320-ft. Dressler tunnel kiln. It is estimated that the efficiency of fuel consumption is 75 per cent, against 10 per cent efficiency in the periodic type of kiln. Without a doubt the tunnel kiln is the coming method of burning in the ceramic industries just as the byproduct coke oven has superseded the beehive type for the production of coke. Fig. 8 shows a car of ware entering the kiln. Fig. 9 shows the exit end. Note the sheet-iron jacket at this end, which absorbs the heat in the cooling zone and transfers it to the carrier drive on the upper floors. Fig. 10 shows the pipe for conveying the heat away from the kiln in the cooling section. Fig. 11 shows the walls and arch of the kiln during process of construction. Fig. 12 shows the construction of the section at the head end of the kiln. Figs. 13, 14 and 15 are additional views of the kiln during the erection.

While the temperature in the main heating zone reaches 2,100 deg. F., the construction of the brickwork and car is such that the track and iron trucks of the car were so cool a piece of paper laid between the rails would not be scorched by the heat above.

THE FANSTEEL PRODUCTS CO.

Fig. 16 shows a general view of this plant, and while the process of manufacturing tungsten has been described in *CHEMICAL & METALLURGICAL ENGINEERING*, vol. 22, No. 1, page 9, the research laboratory of the company is now concentrating on improving the process for the manufacture of molybdenum mainly because it is a more ductile and easily workable metal.

The company manufactures molybdenum metal principally for supplying the electrical trade, and for the manufacture of its own electric furnaces used in working tungsten metal. A very considerable amount of molybdenum goes to vacuum tube or audion manufacturers for plates in wireless telegraphy. Its low coefficient of expansion, which enables it to be welded to Pyrex glass, makes it extremely desirable in this connection. It has a melting point of approximately 2,500 deg. C. and a relatively low vapor pressure.

Generally speaking, the Fansteel company starts from commercial molybdic acid, although at present it is running down a small quantity of molybdenite, MoS_2 , by roasting on a cast-iron base. This method is the commercial method and could be worked out to give a very satisfactory product. It is also possible to break up the molybdenite with nitric acid, leaving a molybdic oxide. The latter, however, is expensive and not particularly efficient.

The product of roasting is dissolved in ammonia, filtered and precipitated with nitric acid. This gives a relatively pure molybdic acid which is then ignited at a temperature below 1,000 deg. C. to molybdic oxide, a pale yellow-brown material.

It is necessary in the purification process to be sure that copper and all the alkali earth metals are eliminated. Their presence in the actual metal is of little consequence except that they retard seriously the reducing of the oxide to metal by preventing the removal of oxygen.

Molybdenum is reduced from the ignited oxide in nickel or nichrome trays placed in iron tubes. A stream of hydrogen previously dried and purified is run through

the tubes, which are subjected to temperatures approximately 1,000 deg. Reduction of molybdenum is extremely difficult as compared with tungsten; it is frequently necessary to run a furnace containing trays of the oxide for forty hours before reduction is complete enough to make a workable metal.

The metal powder is removed from the boats, screened and pressed into bars in a hydraulic press, the process varying from that of tungsten only in minor details.

The pressed sticks of metal are placed between electrodes of an electric furnace and brought up to approximately 2,400 deg. C. by passing an electric current through them. This operation is, of course, performed in an atmosphere of hydrogen. The molybdenum shrinks very considerably and the follow-up on the electrodes must be unusually long in order to develop sufficient grain growth in one operation. The ingots must not show any cracks except very slight ones at the end, unavoidable because of the cooling effect of the electrode.

The material is then rolled into sheets, or may be swaged round in ordinary swaging machines. The drawing operation in the manufacture of molybdenum wire may begin as large as 0.100 in. A piece $\frac{1}{4}$ in. in diameter may be bent cold in a radius of approximately 3 in. The material is machinable and is highly resistant to most alkalis and acids. It takes a very high polish.

The Fansteel company is issuing a series of loose-leaf sheets which it is intended will cover the subjects of tungsten and molybdenum with some thoroughness. Arrangements have been made so that copies of these sheets may be secured on application.

The laboratory of the company is engaged in assembling data for publication from its extensive work with both metals.

SEARS, ROEBUCK & Co.

Four departments of the plant were visited by the members—namely, the color plant, the paper mill, the wallpaper printing mill and the shade-mounting department.

The raw material for the manufacture of wallpaper is gathered from the waste baskets in Sears, Roebuck & Co.'s large establishment, and in addition is purchased from employees at a price of about 2c. a lb.

All this paper is unbaled on platforms in front of a dust remover, which consists of a revolving screen within a chamber where exhaust air is applied. It comes from this dust remover onto a belt, where it is picked by hand and the various qualities of scrap thrown into chutes. From these chutes it is carried by belt conveyor to the various bins. The company is erecting a new plant which will produce forty-five tons of wallpaper daily, against the present production of eighteen tons.

The paper is pulped in hot water at a temperature of about 140 deg. F. in a mixer, while color, together with a rosin sizing binder, is added. The pulp passes from the mixer to a screen, where the heavy particles are removed and returned for further mastication. Material which passes through the screen goes to a Fourdrinier paper machine, which makes a roll of about 40 in. in width. From the Fourdrinier the paper passes through a first and second set of pressing rolls and then into the drying rolls, thence to large calenders, and finally into the slitter and winder, where it is cut to 19½ in. widths—the standard size for wallpaper.

The color plant employs vegetable, mineral and coal-tar dyes. The individual ingredients are dumped into

the agitated mixing tank shown in Fig. 17 and various colors are drawn off from these tanks into larger vats shown in Fig. 18. From these vats they are pumped into a filter press shown in Fig. 19. The cake from these processes is ready for mixing with the clay base. The additional unit which is being installed at the plant, instead of a filter press, includes a 6 x 6-ft. Oliver filter wheel.

The clay, which is a South Carolina kaolin, is beaten to a creamy mixture in the apparatus shown in Fig. 20 and then pumped to mixing tanks on the upper floor.

In these tanks the ground coat for printing on the paper is colored by the material brought from the filter presses. The other inks which go over this ground coat are mixed by hand with the clay in tanks near by. One of the printing machines applies a varnish coat which goes on over the color. It is a cold cut gum spirit tile varnish. A specialty oil-color mixing plant is also in operation and is equipped with Kestner & Hecht apparatus throughout. The departments auxiliary to the wallpaper plant are a modern white tile laboratory, a complete machine repair shop, a wallpaper catalog printing department and a roller manufacturing department.

The rollers from which the designs are printed onto the wallpaper are made of wood, the designs being hammered in from cut pieces of brass. After the pattern is thus made on the roll the metal is turned down to exact diameter for the presses.

HEATH & MILLIGAN Co.

This is a modern and well-operated plant for the grinding and mixing of various paints and colors. Some of the raw materials used are English whiting, barytes, white mineral primer, arctic zinc, polar zinc, Carter white lead and National white lead. The various departments involve the grinding and mixing of enamels, varnish, paint, heavy outdoor paints and dry colors.

The laboratory of this plant has done a large amount of research work in the past and is completely equipped for paint analyses and control.

The company has issued a booklet entitled "Select Methods of Paint Analysis," which involves methods of analysis for mixed paint, white pigments, sulphur trioxide, various color pigments, including red lead and orange mineral, analyses of Chinese white and blue, ultramarine blue, chrome green and many other special products.

Since this company has been recently purchased by the Glidden Varnish Co., the research work will probably be carried on elsewhere.

New Sulphuric Acid Plant for Montevideo

A factory, equipped with the most modern apparatus for the production of sulphuric acid in large quantities has been installed recently in Montevideo as an annex to the Chemical Institute in that city. It is reported by Consul David Myers that the capacity of the plant is greater than the needs of the country, and that its product, of 66 deg. test, can be sold at 8.5 centesimos per kilo (3.98c. per lb.), while the imported article is quoted at 10 centesimos per kilo (4.69c. per lb.). It is expected that the loan of 130,000 pesos (\$134,420), which was made by the Bank of the Republic for the installation of the laboratory, will be paid by the profits of the establishment within ten years. The name of the director of the Chemical Institute, who is an American, may be obtained from the Latin American Division.

The Manufacture of Lime for Chemical and Metallurgical Purposes*—I

A Description of Shaft Kilns, Their Design, Construction and Method of Operation—An Improved Shaft Kiln With Reinforced Concrete Shell—Furnace Box and Arch—Cooling Cone—Distribution of Heat—Fuels and Their Consumption

BY RICHARD K. MEADE

KILNS employed for burning lime may be divided into two classes—intermittent kilns and continuous kilns. The latter class in turn may be subdivided into rotary kilns and shaft kilns. The shaft kilns may be again subdivided into mixed-feed and separate-feed kilns.

The intermittent kilns are usually known as "pot kilns" from their shape. They are primitive, uneconomical and are seldom used except for burning lime for the farm, where they are employed to some extent because they are inexpensive to construct, as they can be built of rough local stone. These pot kilns are built in the side of a hill in order that the limestone may be dumped into the top by means of carts.

In charging such kilns, an arch of the larger pieces of limestone is first built 2 to 3 ft. from the ground and the limestone to be burned is piled on top of this, using pieces averaging in size from 2 to 8 in. thick. A wood fire is started below the arch and the flames from this pass up through openings in the latter and between the stone. The fire is usually maintained for about two days, when the kiln is cooled. Old kilns of this sort are to be seen along the roads in any limestone country.

CONTINUOUS SHAFT KILNS

As has been noted, the continuous shaft kilns may have either a mixed feed or separate feed. Both types are used for producing chemical and metallurgical lime. In the former class, the fuel comes in contact with the limestone; in the latter, the fuel is burned on grates and only the products of combustion come in contact with the limestone. The common type of mixed-feed kiln employed by lime manufacturers is similar in design to a large pot kiln, but is equipped with gates at the bottom of the kiln through which the lime may be drawn as burned.

Vertical kilns of mixed-feed type used in chemical plants are very similar to the separate-feed kilns described further on except that they are not provided with fireboxes on the side of the shaft. They consist generally of a shaft 40 to 50 ft. high lined with firebrick and covered either with a steel jacket or with steel bands. They are equipped with gates through which the lime may be drawn at regular intervals from below. When such kilns are used in the sugar and soda industries they are provided with a closed top and the products of combustion are drawn off by means of a fan in order that the carbon dioxide may be utilized. No detailed description of such kilns need be given, as in a well-constructed mixed-feed kiln the

structural features are quite similar to those described further on for separate-feed kilns.

In charging such a kiln, the fuel (coke or small size anthracite coal) and limestone are added in alternate layers. Fire is started at the bottom and works its way up. The process of charging and drawing the kilns is continuous. These kilns are economical of fuel and for the same size kiln give a larger quantity of product than that given by the vertical kilns with separate feed. Their exit gases are also usually somewhat richer in carbon dioxide. On the other hand, the lime is contaminated by the ash of the fuel. When such lime is used for building purposes or for metallurgical work, it must be carefully sorted in order to discard the lumps to which the fuel ash has adhered. Where the lime is to be slaked for milk of lime, the separation of the ash and the lime can usually be effected by passing the milk through a screen, or where used to causticize, by placing the lime in a wire cloth basket and dipping in the causticizing tank.

IMPROVED SHAFT KILN

The vertical kiln with separate feed usually consists of a steel cylinder lined with firebrick, into the top of which the limestone is charged. The kiln is heated by from two to four dutch ovens built into the side of this so that the products of combustion pass into the latter while the ash of the fuel remains on the grates. The burning is done in the zone between the ports of the furnaces. The lime is drawn out below.

Fig. 2 illustrates a shaft kiln designed by the writer which may be taken as fairly representative of this type of kiln. There is nothing very original about the general design, but the lines have been so worked out as to give the proper fuel economy and quality of lime. Added to this are certain features intended to facilitate the operation of the kiln, cut down repairs, cheapen the construction, etc.

The dimensions of the kiln are altered usually to suit local conditions and the lime to be burned. With soft limestone, the kiln is not usually made so high as with the hard stone, because the former will not stand so great a weight of stone without crumbling. Where the limestone is hard to burn, the diameter is usually less, while with easy burning material such as dolomite, the diameter is greater. The diameter is also increased where gas is used as fuel.

Generally speaking, the kiln consists of a steel shell 11 ft. in diameter and about 38 ft. high. This shell rests on a solid block of concrete and terminates in a steel cooling cone. This shell is divided into two parts. The upper 5 to 6 ft. is unlined and forms a

*Read before the American Institute of Chemical Engineers, Montreal, June 28, 1920.

bin for the storage of the stone so that the kiln does not have to be continuously charged. The lower section of about 32 ft. is lined with firebrick, and in this the stone is burned.

FURNACE AND COOLING CONE

The kiln is equipped with two furnaces, one on each side. These are supported on a reinforced concrete floor level with the bottom of the shell and 12 ft. above the floor on which the lime is drawn. Usually the reinforced concrete firing floor is extended from 10 to 20 ft. beyond the firebox front in order to give ample space for the burners to work and on which to pile the coal for burning, etc.

The cooling cone is of steel plate and is so placed that the air can circulate freely around it. This cone receives the red hot lime from the burning zone of the kiln. The function of the cone is to cool the lime. The bottom of the cone is closed by means of a pair of doors which swing from pivots supported by two small I-beams. The doors are pulled outward by means of a pair of levers when the lime is to be discharged and pushed shut when this has taken place. The cone is far enough from the floor to allow a car to be run under the doors into which the lime is discharged. The levers operating the doors are located outside of the kiln and permit the operator to stand away from the dust and heat while the lime is being drawn. The doors can be adjusted to give a close fit to the bottom of the cone. There is a free passage entirely around the cone and no blocking up occurs as in most other forms of discharge. The cone is provided with a poke hole closed by a sliding shutter to be used in case the lime does not discharge freely due to arching. In some of the writer's newer kilns he has placed a water-jacket around the upper part of the cone in order to increase the life of this.

The track by means of which the kilns are charged passes over one side of the kiln so that the cars dump directly into the center of the kiln, giving an even distribution of the charge. The track is supported on light steel I-beams and a platform of perforated metal supported by brackets and inclosed by railings runs around the top of the kiln and between the rails. A heavy ring of steel plate protects the top of the brick from damage by the falling stone.

Where these kilns are used for building lime it is usual to carry the lime from them by means of barrows or cars. A more approved method, however, would be to place a pan conveyor under the cooling cone and draw the lime immediately onto this and so convey it to the point of use.

REINFORCED CONCRETE SHELL

• During the last few years the cost of the steel jacket for the kiln has been quite an item and a cheaper material which could be substituted for this has been desirable. Having great faith in reinforced concrete, this latter material naturally suggested itself to the writer.

As the result, plans were drawn about three years ago for two kilns with reinforced concrete shells which were built at a small plant in Virginia. These have been in use for several years, long enough to show that the material and form of construction are entirely satisfactory. Since these were built the writer has designed reinforced concrete kilns for several other lime plants. There are other advantages in

this form of construction besides cheapness, the principal ones being that the shells do not have to be painted, as they are not subject to corrosion, and there is less loss of heat by radiation.

The reinforced concrete kiln does not differ very materially from that which I have illustrated. Proper means are, of course, taken to heat-insulate the concrete shell. The cooling cone is made of steel and there is the same unlined top serving as a stone bin.

The arches over the furnace ports are a weak point in the shaft kiln. These arches are not only subject to destruction from the heat but they carry the weight of the lining, etc., above them. In the reinforced concrete kiln, this weight has been taken off of the arch by means of a reinforced concrete girder extending over the firebox.

DRAFT AND DISTRIBUTION OF HEAT

With all types of shaft kiln one of the points to be watched is the draft. This must be so regulated by the design that the contents will be uniformly heated, otherwise some of the lime will be overburned and some of it not burned enough. In some instances stacks are placed on the shaft in order to induce a better draft. Induced draft is also employed, the products of combustion being sucked from the top of the kiln by means of an exhauster. Where this is

FIG. 2

FIG. 3

FIG. 4

Fig. 1. Old style pot kiln. Fig. 2. Shaft kiln with separate feed. Fig. 3. Closed top for shaft kiln. Fig. 4. Producer gas-fired kiln.

done it is, of course, necessary to close the top of the kiln and to charge the limestone into the latter through a door or a charging "bell" somewhat similar to that of a blast furnace. Fig. 3 shows such an arrangement. When the kiln gases are drawn off for their carbon dioxide this bell type is generally employed.

A less satisfactory method of artificial draft is to force the fire by means of a blast below the grates. This usually takes the form of a steam blower. If

the fire is blown, there is a tendency for the flames to come out around the furnace door rather than to pass through the shaft, but the steam itself is beneficial.

If the kilns are too large in diameter, the heat will usually not carry to their centers and so the stone in the center of the kiln will not be burned properly. The writer has found that, owing to the fact that the gases from the firebox show a tendency to hug the sides of the kiln, the latter may be made of greater diameter across the center line of the fireboxes than along this line. This makes a horizontal cross-section of the kiln at the fireboxes elliptical in shape. Two sides of the kiln are straight down to the cooling cone, while the other two sides are drawn in slightly as shown in Fig. 2. If drawn in too much, and with some stone if drawn in at all, the charge will stick and hang up in the kiln.

The lime is usually drawn every three to six hours, although a few plants draw oftener and some less frequently. Large kilns are sometimes provided with a continuous draw. The objection to drawing too often is that each time the lime is drawn cold air enters the kiln through the drawing doors and cools off the charge. This same objection has been raised to kilns provided with a continuous draw—namely, the continual current of air entering where the lime is drawn passes up through the center of the kiln and prevents the proper burning of the lime at this point.

The charge sometimes sticks in the kiln, and openings closed by proper means are usually left on both sides of the shaft just above the furnaces through which bars may be introduced. It is claimed that kilns lined with silica brick show less "hanging up" than kilns lined with ordinary firebrick, due to the fact that the silica brick lining very soon scorifies and becomes smooth.

FUELS AND THEIR CONSUMPTION

This type of kiln may be heated by wood, coal, oil, natural or producer gas. Wood is supposed to burn a better quality of lime than any other fuel, due to the low temperature of the flame and the length of this, and for this reason it is sometimes used for burning building lime; but it is very seldom used for burning chemical and metallurgical lime owing to its cost. The majority of kilns of the type given employ coal. This should be what is known as "long flame" coal, high in volatile matter and preferably low in sulphur and ash.

Where obtainable, oil makes an excellent fuel. When it is used in the kiln described, the burner is placed in the door openings of the fireboxes and these are bricked in with firebrick, leaving openings for the burner and for observing the lime, etc. The grate bars, if already in place, are covered with firebrick, or if a new kiln, the firebox is simply filled up to the point of the grate bars with some suitable material and covered with firebrick.

Natural gas may be used in this kiln and also producer gas, but better results can be obtained by modifying the lines of the kiln to suit this latter fuel.

Producer gas is quite extensively employed for burning lime. Its advantages and disadvantages are a matter of dispute. One of the principal good points is the fact that very much larger gas-fired kilns can be built than is possible with hand firing. Some of the more recent gas-fired kilns have a capacity of from

forty to sixty tons of lime per day each. This increased size of the kiln is made possible by the introduction of gas and air at various points around the kiln so as to obtain uniform temperatures throughout the stack. Fig. 4 shows a gas-fired kiln.

Producer-gas kilns are slightly more economical of both fuel and labor than grate-fired kilns. Unless carefully handled, however, they give lime which is unevenly burned. More skill is required in burning lime with producer gas than with any other fuel, and considerable experimenting is usually done before satisfactory results are obtained.

In applying producer gas to vertical kilns, the main points to be watched are proper mixing of the gas and air in the shaft and preventing the accumulation of lime in the gas ports. This latter blocks the flow of gas, causing irregular distribution of the heat and hence under-burning of the lime in certain parts of the shaft. In the type illustrated this trouble has been avoided by sloping the gas ducts downward toward the kiln. The points given further on in this

FIG. 5. LIMEKILNS OF THE CLINCFIELD PORTLAND CEMENT CO.

series under "Producers for Heating the Rotary Kiln" follow also with the vertical.

The shaft kiln described, heated with wood, coal or oil, will produce from eight to twelve tons per day depending on the kiln and quality of the limestone employed. When fired with gas the capacity will be from seventeen to twenty-five tons.

QUANTITY OF FUEL REQUIRED

The quantity of fuel required varies also and depends on many things, among which may be mentioned the kind and quality of fuel, skill of the operator and the limestone itself. Magnesian stone burns more easily than high-calcium stone. The amount of fuel actually required is about as follows:

One ton of good bituminous coal hand fired will burn from three and one-half to four tons of lime.

One ton of good bituminous coal in the gas producer will burn from three and one-half to five tons of lime.

One barrel of fuel oil will burn one to one and one-quarter tons of lime.

One cord of seasoned hard wood will burn from two and one-quarter tons to two and three-quarters tons of lime.

The problem of carrying the stone to the top of the kilns is usually taken care of, where the kilns are lo-

cated at the quarry, by means of a hoist and an incline, the latter running from the quarry floor to the top of the kiln. At chemical plants where the stone is brought in by rail the incline may be used, or in many cases a platform elevator is to be found more satisfactory because of the room saved.

A plan adopted at one of the plants designed by the writer would no doubt be satisfactory in many chemical works. In this plant the railroad cars are pushed on a trestle over storage bins. Each bin has an iron chute closed by a swinging gate through which the stone is discharged. A track extends in front of the stone bins and 9 ft. below the bottom of them and the stone is discharged through the chutes into small side dump cars, which are pushed along the track into the lime plant. The track is covered by a shed so that the drawing of the stone is not interrupted by bad weather. The cars after entering the kiln building are carried to the top of the kilns by a platform elevator.

Fig. 5 shows a battery of shaft kilns. Where only eight to twenty tons of chemical lime is required one or two shaft kilns will prove the best plant, but where larger outputs of chemical lime are needed the rotary plant will prove more economical.

Parts II and III, dealing with Rotary Kilns and Operation, respectively, will appear in subsequent issues.

The Camphor Industry in Foochow

TREES fit to be used for camphor distillation must be at least twenty years old. When a suitable tree is found a crude native distillery is set up at the spot. This consists of a boiler, with an iron base and a wooden top, connected to a distilling vat partly filled with water. The camphor upon being conducted to the vat precipitates as crystals on the inner walls, while the non-precipitable portions drop down as oil, which floats upon the water. About 5½ lb. of camphor and camphor oil, in the proportions of 70 per cent camphor and 30 per cent camphor oil, can be produced from 240 lb. of chips.

The districts where most of this initial distillation is done are Kienning, Yuchi, Yungan, Yenping, Tatien, Shaowu, Shawsien and Ningte, reports Vice-Consul E. B. Price, in *Commerce Reports*.

It is almost impossible to say how many men are engaged in the industry, but there cannot be many. Their wages are equal at the present rate of exchange to about \$0.38 a day.

The crude product is carried by porters to the Min River or one of its tributaries, and then carried to Foochow by native boat. Boat hire is approximately \$1 per cwt. from the interior to Foochow.

HOW MARKETING IS DONE

The marketing of camphor is done very largely through brokers in Hongkong. The distilleries seldom do their own marketing, with the exception of the Japanese and Portuguese. There are also brokers in Foochow able to handle foreign orders in the English language.

It should be borne in mind that the camphor market is an extremely sensitive and dangerous one for the uninitiated. The factors of supply, governmental supervision, freights, stocks in Foochow and Hongkong, and three markets—Foochow, Hongkong and the foreign

market—all enter into the situation. Hence no better scheme than the brokerage system can be suggested, unless the foreign buyer is prepared either to go into the producing end of it or into the buying and holding of considerable stocks himself.

DISTILLATION OF THE OIL

The product as it leaves the distillery in the interior consists of crystals and camphor oil. The crystals are ready for marketing, but the oil is put through a process of redistillation at Foochow. This process is a simple one, and need not be described here in detail. The effect is to distill from the oil all the remaining camphor; 133 lb. of oil produces 64 lb. of camphor and 27 lb. of desolated oil. The camphor derived from oil is of a cheaper grade than that derived originally from the wood chips. The desolated oil is used as a base for dyes and paints.

There are twelve of these distilleries in Foochow which produce camphor from the oil. They are known as the Yuan Cheng, Hsing Chi, Cheng Chi, Hsiang Chi, Fu Sheng, Hsieh Chi, Kao Fang and Tao Ho—all Chinese; Ting Te—Portuguese; and Mitsui Bussan Kaisha and Tai Hua—Japanese. When working, each distillery produces on an average 325 lb. of camphor a day.

THE GOVERNMENT CAMPHOR BUREAU

The various districts producing camphor have each an official camphor bureau under the control of the Provincial Commissioner of Industry. Each bureau has the authority within the district it covers to collect certain taxes and to buy camphor trees and distill camphor. In American currency the tax is approximately \$6 on every 133 lb. of camphor in transit. The taxes collected and the camphor produced are sent to another government bureau called the Fukien Government Camphor Industry, Transportation and Tax Collection Office. Its duties are to take in and turn over to the provincial government the taxes remitted by the various district bureaus and to take in and market the camphor that is received.

There is still a third bureau which has authority to buy camphor oil and distill it into camphor, marketing its product independently.

Private producers must take out licenses and agree to pay the taxes hereinbefore mentioned. In addition to this there is a license fee of \$2 local currency per month per vat.

REGULATIONS FOR FOREIGNERS

Foreigners wishing to go or send into the interior to purchase camphor under what is known as the "transit pass" system, permitted by treaty, may still do so. Under this system the foreign exporter may bring the native product to the seaboard and export it to a foreign country by paying the regular 5 per cent export duty plus a surtax of half the export duty. The foreigner may purchase either from the private producers or from the government bureau. The effect of the government bureau system is to tax the product just the same, because the foreigner may not operate his own distillery in the interior, and government taxes are imposed on the distillery and its product before the foreigner purchases the camphor.

Japanese distilleries operating in the city of Foochow are not taxed, according to information given by the Japanese consulate in Foochow.

Synopsis of Recent Chemical & Metallurgical Literature

Titanium Pigment Industry in Norway.—In view of the growing importance and increasing output of titanium dioxide as a pigment in active competition with lithopone, the *Chemical Trade Journal and Chemical Engineer* has published (Sept. 25, 1920, p. 407) a short account of the process used by the Titan Co. of Fredrikstad, Norway.

Although extensive deposits of titanium ore are found in the New World, Africa and Australia, the only deposits of any importance in Europe occur in Scandinavia and in the Urals, where the titanium oxide is found in combination with iron oxide, as titaniferous iron ore or ilmenite. The most interesting deposits in Scandinavia are found in Norway, in Sogndal, south of Rgersund, at Raagefjord, and Jössingfjord. These are Laxedalsfelterne, with ore containing about 35 per cent of TiO_2 , in quantity 250,000 tons; Blaafjeldet, with ore containing about 40 to 45 per cent TiO_2 , in quantity about 100,000 tons; and Storgargen, with ore containing about 25 to 40 per cent TiO_2 , in quantity about 3,000,000 tons. It is from the two latter deposits that the Titan Co. obtains its ore.

The ore is sorted, pulverized, classified and washed over washing boards. The dressed ore is now carried seven kilometers by rail to Raagefjord and from there shipped to Fredrikstad. After being dried and finely ground the ore is thoroughly mixed with sulphuric acid in a special mixing apparatus, and the mixture is then transferred to a decomposition plant, where the reaction between the acid and the ore is started by gas heating. The apparatus works continuously and delivers the decomposed titanium ore and sulphuric acid mass in the shape of cakes, in suitable sizes, which are crushed and ground and then dissolved in water. The titanium and iron solution obtained in this way contains particles of non-decomposed minerals. It is necessary to separate these particles from the solution. Filtration has been tried in every possible way, but the problem could not be solved in a practical manner. In the present process the undecomposed mineral is separated by settling in large vessels. Certain devices are used by which the speed of the settling is greatly accelerated. The quite clear solution is then electrolytically reduced, whereby the ferric iron is converted into ferrous iron. On boiling in a vessel provided with internal steam coils the titanium dioxide falls out as a white amorphous powder.

The elimination of ferrous sulphate and free sulphuric acid from this powder constituted one of the most difficult technical problems. It was impossible to find a suitable filter, both on account of the extreme fineness of the titanium oxide particles, and on account of the corroding effect of the acid solution. A washing system was eventually adopted, in which practically all the iron is removed. Traces of sulphuric acid are eliminated by the addition of barium carbonate, and so the final product contains a certain amount of barium sulphate. Very minute traces of iron—0.02 per cent—are sufficient to discolor the product, and the details of how the last small traces of iron are removed are not divulged, although it is suggested that it is effected

by adding substances which form colorless compounds with iron. The product is calcined, ground to such a fineness that 99.95 per cent passes through a mesh of 5,000 to the sq.cm. The pigment is then mixed with linseed oil and a little zinc white is added. After thorough incorporation in the edge-runner mill, the product is ready for use.

As compared with white lead and zinc oxide, the advantages titanium-white offers are said to be considerable. It possesses a greater covering power than either, is non-poisonous and is chemically inert. Unlike zinc oxide, it exerts no saponifying action upon the linseed oil. Its low specific gravity (4.0) renders it very easy to apply.

In connection with the experimental work on titanium-white, Prof. V. M. Goldschmidt, who microscopically investigated the differences in covering power of titanium-white in various states of subdivision, arrived at the conclusion that among other things the covering capacity of a pigment depends upon the difference between its own refractive index and that of the binder used, and in this connection it is interesting to note the following figures: If the refractive index of linseed oil be assumed to be 1, then the refractive index of zinc oxide 1.34, of white lead 1.36, of amorphous titanic oxide 1.48, and of crystallized titanic oxide in the shape of rutile 1.80. This difference in refractive indices would seem to account for the greater covering capacity of titanium-white.

It is interesting to note in connection with the foregoing abstract that the titanium pigments which are being made in the United States by the Titanium Pigment Co. of Niagara Falls resemble lithopone both as to barium sulphate content and as to specific gravity. Thus, BXX Titanox (sp. gr. 4.28) consists of 25 per cent TiO_2 and 75 per cent BaSO_4 , while a well-known brand of lithopone contains 30 per cent ZnS and 70 per cent BaSO_4 , and has the same specific gravity (4.28).

Commercial Possibilities of Government Nitrate Plants.—The first issue of *Army Ordnance*, the organ of the Army Ordnance Officers Association, contains an interesting general article on the nitrate situation, written by Colonel JAMES H. BURNS, Chief of the Nitrate Division. It contains some new pictures of the Muscle Shoals nitrate plant. The author enters into the uses of nitrogen compounds in war and peace, the sources of supply and the Government developments in nitrogen fixation during the war. After touching upon the by-product coke-oven supply in peace time he writes as follows:

"We have made quite careful and thorough analyses of the costs of producing nitrogen compounds at the No. 2 Plant (Muscle Shoals), and as a result thereof we believe that the materials can be produced at a price that should be satisfactory to both the Government and the consumer . . . and it is our judgment that the market can easily absorb the products without appreciably interfering with the present sources."

Before outlining the War Department scheme for the solution of the problem of operating the nitrate plants as incorporated in the United States Fixed Nitrogen Corporation bill, now enjoying a position of prestige on the calendar when the Senate again convenes, the Government made every effort to lease or sell the plants to private interests, but met with no success. The article is a clear, concise and reasonable exposition of the Government's case.

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Treating Vegetable Fibers.—Vegetable fibers of all kinds, whether in the mass or in the form of lap, yarn of fabrics made therefrom, are given the character of wool and an increased affinity and absorbent capacity as regards basic and other dyestuffs, by precipitation thereon of products resulting from the action of concentrated nitric acid upon starch or other amylaceous substance, the precipitation being effected either by washing with water or by treating with dilute solutions of acids, bases or salts followed by washing with water. The fibers may be impregnated with the solution of starch, etc., in concentrated nitric acid, the excess being pressed out, and the nitrated amylaceous substance precipitated upon the fibers by washing; or the fibers are impregnated with a paste or aqueous solution of starch, etc., dried, passed into concentrated nitric acid, and the nitrated amylaceous substance precipitated upon the fibers by washing. Print effects may be obtained on plain fabrics by direct impression or by the use of resists either by means of a solution of starch or other amylaceous substance in concentrated nitric acid, or by means of a paste or aqueous solution of starch, etc., which is treated, after drying, with concentrated nitric acid, the fabric being, in each case, treated with water or with dilute solutions of acids, bases or salts followed by washing with water to precipitate the nitrated amylaceous product. In an example of treatment, a paste is prepared by heating together 40 kilos of maize starch and 75 liters each of water and acetic acid. The textile is dressed with the paste, dried, treated for three to five minutes with 72 per cent nitric acid at a temperature of 15 to 20 deg. C., the excess of acid is pressed out, and the material is passed through a 10 per cent solution of sodium bisulphate, and washed with water. Specification 136,568 is referred to. (Br. Pat. 144,204—1919. GILLET ET FILS, Lyons, France, Aug. 5, 1920.)

Lead and Silver Chlorides.—Sulphide ores and products containing silver, lead and zinc sulphides are partially chloridized, for instance by heating with enough zinc chloride to chloridize the silver and lead, and the product, from which the excess of zinc chloride may be removed by leaching with water acidified with hydrochloric acid, is then leached with a solvent such as cold brine containing ferric chloride and which may be saturated with lead chloride, so as to extract the silver alone, and the residue is then leached with hot brine for dissolving the lead chloride. (Br. Pat. 144,260—1919. AMALGAMATED ZINC (DE BAVAY'S), LTD., Melbourne, Aug. 5, 1920.)

Sodium Hydrate.—Caustic soda is obtained by emulsifying a soda solution with lime by means of a "turbo-mixer" having at least one turbine-wheel or centrifugally-acting blade-wheel. The reaction is effected in the cold, for instance in about fifteen minutes. (Br. Pat. 144,266—1919. SCHWEIZERISCHE SODAFABRIK ZURZACH, Argovie, Switzerland, Aug. 5, 1920.)

Hydrogenating Oils and Fats.—An apparatus for use in the hydrogenation of oils and fats comprises a vessel 1 jacketed for heating and provided internally with means for converting the mixture of oil and catalyst into a mist or rain, and externally with a pump 16 for withdrawing the oil from the lower part of the vessel and returning it to the upper part for the treatment with hydrogen to be repeated; the means for spraying the oil comprises a series of buckets 4 mounted on a rapidly-rotating vertical shaft 3 and provided on their peripheries with sockets in which brushes 9 with short flaring bristles are mounted, so that oil delivered into the buckets by disk-shaped plates or partitions 6 is by centrifugal force caused to travel along the interstices of the brushes and to be delivered into the atmosphere

of hydrogen within the vessel as a mist or rain. The shaft 3 is mounted in a steady plate 11, and below this is a stirring device for the oil that collects, consisting of blades 12 carried by the shaft 3 and blades 13 fixed to the casing; and below this, also carried by the shaft, is an agitator 14 to prevent settling of the catalyst. Connections 17, 18 are provided for the supply of oil and hydrogen. Specification 1380—1915 is referred to. (Br. Pat. 144,478—1919. BLAIR, CAMPBELL & McLEAN, D. A. BLAIR and J. L. FERGUSON, Glasgow, Aug. 11, 1920.)

Azo Dyes.—Azo dyes are prepared by coupling diazo compounds containing a sulphonic or carboxylic acid group in *o*-position with 5 : 5'-dioxy-2 : 2'-dinaphthylamine-7 : 7'-disulphonic acid. According to examples there are obtained: A monoazo dye from 4-chlor-2-aminobenzoic acid and the second component; a primary disazo dye from two molecules of anthranilic acid and the second component; a primary disazo dye from 4 : 5-dichloraniline-2-sulphonic acid, 4-chlor-2-aminobenzoic acid, and the second component; a primary disazo dye from anthranilic acid, 4-chlor-2-aminophenol, and the second component; a trisazo dye by diazotizing the monoazo dye from anthranilic acid and 3-amino-4-cresol methyl ether and coupling with the monoazo dye from

anthranilic acid and the second component; a primary disazo dye from 1-naphthylamine-2-sulphonic acid, 4-chlor-2-aminobenzoic acid, and the second component; a primary disazo dye from two molecules of 4-dimethyl-amino-1-amino-benzene-2-sulphonic acid and the second component. The products dye cotton red to blue shades fast to ironing and the dyeings may be aftertreated with copper sulphate. (Br. Pat. 144,310—1919. **FARBEN-FABRIKEN VORM. F. BAYER & Co.,** Leverkusen, Germany, Aug. 5, 1920.)

Borneol.—Borneol is prepared by heating pinene with tetrachlorophthalic acid and hydrolyzing the resulting dibornyl ester. (Br. Pat. 144,604—1919. **FABRIQUES DE PRODUITS, CHIMIQUES DE THANN ET DE MULHOUSE,** Thann, France, Aug. 11, 1920.)

Freeing Anthracene From Carbazole.—Crude anthracene is freed from carbazole by boiling with caustic potash in a neutral solvent—e.g., naphtha—while distilling off the water formed. The potassium-carbazole formed precipitates and is removed and worked up to carbazole. (Br. Pat. 144,648—1919. See also 144,656—1919. **KINZLEBERGER & Co.,** Prague, Aug. 11, 1920.)

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Sulphuric Acid Manufacture.—Another sulphuric acid plant design which shows the tendency away from the lead chamber process is that of **KENNETH B. QUINAN** of Somerset West, Cape Province, South Africa. Instead of passing through the customary lead chambers, the gases are forced upward through diaphragms over which a constant flow of sulphuric acid is maintained. Products of the gaseous phase reactions and heat of reaction are rapidly absorbed by the circulating acid. It is convenient to arrange the diaphragm devices in series or in series-parallel. (1,348,736; Aug. 3, 1920.)

Barium Peroxide.—Barium monoxide may be converted into peroxide by treatment in an air-tight ball mill with dry oxidizing gas at a pressure of 20 to 60 lb. per sq.in. The temperature range for uniform oxidation is from 400 to 600 deg. C. By the use of a revolving mill of the type referred to, dense as well as cellular or porous monoxide may be treated with equal facility. (1,349,417; **HERMAN FLECK** of Golden, Col., assignor to the Peroxide Specialty Co.; Aug. 10, 1920.)

Electrolytic Chlorine Cell.—An improved form of electrolytic cell for the decomposition of brine consists of a suitable tank, a rectangular box-shaped cathode having perforated active end, side and bottom walls, a diaphragm covering the inner faces of all of these walls, and a rectangular tubular anode. Certain advantages result from this construction. For example, practically the entire inner face of the cathode, including the bottom, sides and end walls, is electrically active, and the exterior faces of the cathode are wholly unsubmerged in any body of electrolyte. By providing a water-tight and gas-tight pressure joint between the cathode and the free-board section, it is possible to build up the column of electrolyte in the free-board section so as to secure the desired hydrostatic head as the diaphragm becomes more or less clogged with the impurities in the brine, thus insuring a longer diaphragm life than would otherwise be possible. (1,349,597; **HERBERT I. ALLEN** and **KENT R. FOX** of Portland, Maine, assignors to Electron Chemical Co.; Aug. 17, 1920.)

Carbon Disulphide.—A charge of coke is brought to a red heat in a tumbling barrel having a refractory lining. A current of sulphur dioxide is passed through the tumbler forming carbon disulphide according to the reactions:

As the action is endothermic, a small amount of air is admitted with the sulphur dioxide in order to maintain the proper temperature by the combustion of a part of the coke. Since the carbon disulphide vapor which escapes is mixed with CO and CO_2 , it cannot be condensed by simply lowering the temperature but must be absorbed in a suitable solvent (such as certain vegetable oils) from which it can be recovered by distillation. (1,350,858; **HERBERT H. DOW** and **CHARLES J. STROSACKER**, of Midland, Mich., assignors to the Dow Chemical Co.; Aug. 24, 1920.)

Extracting Tar From Vapors.—The removal of tar from vapors resulting from the distillation of coal or wood is accomplished by bubbling the vapors first through tar and then through cresol or anthracene oil. In the case of wood distillation the process is outlined as follows by **EMILE A. BARBET** of Paris, France. After passing through the tar, the vapors are at a temperature of 115 to 130 deg. C. In bubbling through the cresol, only the tar will be dissolved since at this temperature the water vapor and acetic acid vapor are superheated and cannot be retained by the cresol. (1,351,363; Aug. 31, 1920.)

Sodium Hydroxide.—The reaction between disodium phosphate (Na_2HPO_4) and milk of lime is utilized by **SAMUEL S. SADTLER** of Springfield Township, Pa., for the preparation of sodium hydroxide.

$2Na_2HPO_4 + 2Ca(OH)_2 = 4NaOH + Ca_2H_2(PO_4)_2$,
 $2Na_2HPO_4 + 3Ca(OH)_2 = 4NaOH + Ca_3(PO_4)_2 + 2H_2O$
 The sodium hydroxide solution is separated from the insoluble calcium phosphate. Disodium phosphate may be recovered by treating the dicalcium phosphate with sodium sulphate or the calcium phosphate with niter cake. (1,351,693; Aug. 31, 1920.)

Acid-Resistant Alloy.—Considerable interest was aroused by a note in **CHEM. & MET. ENG.**, Nov. 12, 1919, p. 632, concerning a new Italian alloy, "biakmetal." According to the present specification, this alloy consists of:

	Range Per Cent	Typical Example Per Cent
Copper	35 to 44	40
Iron	1.5 to 4.75	3
Tungsten	3 to 6	3
Nickel	60.5 to 45.25	54

Alloys of such composition, in cast condition, have a tensile strength of about 55 kg. per sq.mm. and an elongation of about 20 per cent. They may be forged and rolled both cold and hot. After drawing, the tensile strength in some cases exceeds 100 kg. per sq. mm. The alloy is said to resist the action of acids as follows: Sulphuric acid, any strength at temperatures under 100 deg. C.; hydrochloric, acetic, citric and tannic acids, any strength at any temperature; cold nitric acid, up to 1.40 sp.gr. (1,351,811; **ARRIGO TEDESCO**, assignor to **Societa Anonima Stabilimenti Biak**, of Turin, Italy; Sept. 7, 1920.)

Ferromanganese.—The manufacture of 80 per cent ferromanganese in the blast furnace is made possible by using a blast enriched with oxygen. (1,354,490; Estate of **JOSEPH E. JOHNSON, Jr.**; Oct. 5, 1920.)

Current Events

in the Chemical and Metallurgical Industries

American Petroleum Institute's Annual Meeting

The American Petroleum Institute will hold its annual meeting in Washington, with headquarters at the New Willard Hotel, on Wednesday, Thursday and Friday, Nov. 17, 18 and 19, 1920. All the general sessions and group meetings will be held at this hotel, unless otherwise announced. Group meetings covering specific subjects such as Statistics, Transportation, Taxation, Research, etc., will be held in the forenoon of each day, followed by general sessions on the afternoons and evenings of the three days, with the exception of Friday evening, which will mark the Institute's annual banquet and the closing of the convention.

The general topic for consideration on the first day will be "The World's Petroleum Problem." Speakers of national and international renown will deliver addresses covering the relationship of America, Great Britain, Mexico and other oil-producing countries to the world's petroleum problem. The general topic for the second day is "The Production and Consumption Situation."

The topic for discussion at the general session Friday afternoon will be "The Future of the Oil Business." The program as outlined for the general sessions will represent the last word as to the world petroleum situation, the present-day status as to production and consumption, and a forecast as to the industry's future. Specific subjects such as transportation, taxation, statistics, research, improvements in methods, etc., will be discussed by experts in the group meetings. Throughout the three days' session the emphasis will be upon oil. Because of its national and international character, this meeting of the Institute will mark a distinct step in the industry's progress and development.

Remuneration for C.W.S. Consulting Chemists

Some difficulty is being experienced by the Chemical Warfare Service in finding a basis for the remuneration of the consulting chemists who are to be appointed. It is believed, however, that no legal or other difficulties will prevent the payment of a per diem salary, in addition to traveling expenses. General Fries is very anxious that authority be secured to pay traveling expenses, so that he will feel less hesitant in asking a chemist living at a distance to go to Washington. It is his intention to have a large number of consulting chemists attached to the service, so that the list may include specialists in a large number of subjects. As problems arise, he would like to be in a position to send for the chemist best qualified to handle each particular one. For instance, just at this time, in the study of the physiological effect of certain gases, it is highly desirable to have the assistance, for a very few days, of a chemist in a Western city. That particular chemist is thought to be best qualified to be of service in this specific juncture. It may be months before his actual presence in the laboratory again would be imperative. General Fries wants to be in a position to pay this man's traveling expenses and a per diem salary for the time he is absent from his office.

Metric System Advocated at Meeting of Rochester Engineering Society

Members and friends of the Rochester Engineering Society heard the affirmative side of the question of the national adoption of the metric system presented by Dr. W. N. Souder, of the Bureau of Standards, Washington, D. C., Friday evening, Oct. 8. At the outset Dr. Souder made clear the position of the Bureau of Standards by reading a telegram from Director Stratton, which read as follows: "The bureau believes an international decimal system of weights and measures very desirable. It has never advocated any particular method in bringing this about. We believe that the time, method and the extent of the change in any particular branch of manufacture should be settled only after a careful consideration of the question by representatives of that industry."

Dr. Souder's purpose was not to convert the engineers to the general adoption of the metric system, but to point out the drawbacks of the present English system and to show the need for a consistent standard of weights and measures. The strongest argument against the compulsory adoption of the metric system was the fact that the changing of the weight and measurement sizes would be costly. However, if in the end this resulted in a saving of time and convenience, the first expense would soon be absorbed. Dr. Souder's final plea was that "we ought to have some sort of a consistent standard of figuring."

Nominations for President of the American Chemical Society

At a meeting of the Council of the Pittsburgh Section of the American Chemical Society on Oct. 9, Dr. Raymond F. Bacon, Director of the Mellon Institute of Industrial Research of the University of Pittsburgh, was nominated for the presidency of the Society. It is understood that this nomination has received wide and cordial approval throughout the mid-continent sections.

Dr. Edgar F. Smith, provost emeritus of the University of Pennsylvania, has been proposed by the Philadelphia and Delaware sections for presidency of the Society. His nomination has received the indorsement of the New York Section. Dr. Smith served as president in 1898 and his executive accomplishments elicited the most favorable commendation.

Prof. E. C. Franklin was proposed by the Washington Chemical Society as nominee for president of the American Chemical Society for the coming year, as a result of the action taken at its last meeting, Oct. 14. At the same meeting the following four were suggested as nominees for positions as councillors-at-large of the society: George P. Adamson, James F. Norris, Arthur M. Comey, and A. C. Fieldner.

At this meeting of the section a report was given on the proceedings of the council at Chicago, and Dr. W. M. Clark spoke on "Application of Hydrogen for Concentration Measurements in Analytical and Biological Chemistry."

Division of Technology Discontinued

Effective Oct. 15 the work heretofore assigned to the division of technology, Prohibition Unit, Bureau of Internal Revenue will be subdivided and administered by two divisions known as the Permit Division and the Industrial Alcohol and Chemistry Division. The title "Division of Technology" is discontinued.

Dr. A. B. Adams, former head of the Division of Technology, is appointed head of the Permit Division. J. M. Doran, assistant head of the Division of Technology, is appointed head of the Industrial Alcohol and Chemical Division. The change is made necessary by the increase in the work devolving upon the Division of Technology. The Permit Division will examine and pass upon applications for the manufacture of alcoholic products; determine all non-beverage uses of intoxicating liquors and limitations of such uses; fix standards for manufactured articles containing alcohol; examine bonds; conduct trade investigations to determine whether products are bona fide and whether permitted articles are manufactured in accordance with approved formulas. The Industrial Alcohol and Chemical Division will have supervision of the construction and operation of industrial alcohol and denaturing plants and control of the work of the plant officers; develop uses of denatured alcohol by laboratory work and research; examine denatured alcohol samples; examine samples of toilet articles, flavoring extracts, etc., and report result of analysis to the Permit Division.

Contribution for Co-operative Research From General Electric Co.

The General Electric Co. has contributed \$30,000 to extend the investigations of the Committee on Fatigue Phenomena of Metals, of the Division of Engineering of the National Research Council. Engineering Foundation Board about a year ago made a grant of \$15,000 a year for a period of two years for the investigation of fatigue phenomena in carbon steels. Articles of agreement were drawn up among the National Research Council, Engineering Foundation and the University of Illinois, whereby the experimental work was to be done at the University of Illinois under the direct supervision of Prof. H. F. Moore.

The contribution of the General Electric Co. was made in order to extend the work to include 3 per cent and 3½ per cent nickel steel. This extension is to be considered part of the original program and no restriction is placed by the General Electric Co. on the publication of the results. Although the results of this work on nickel steels will be of immediate commercial value to the General Electric Co., they will also be of value to other manufacturers.

Quarters Sought for Chemists at Edgewood

The Chemical Warfare Service not only is having difficulty in obtaining civilian chemists at the salaries allowed by the Government, but is having trouble in keeping such chemists as are obtained, due to the absence of proper housing in the vicinity of the arsenal. General Fries has applied to the General Staff for permission to erect twenty-four five-room cottages. The General Staff is not inclined to give its permission, as it has not been the policy to supply quarters for civilians. General Fries states that it will be necessary to depart from the rule if chemists and technical men are to be induced to stay at Edgewood.

Merger of Pittsburgh Plate Glass Co., Columbia Chemical Co. and Patton-Pitcairn Proposed

To insure the full requirements of soda ash which the Pittsburgh Plate Glass Co. uses in large quantities in the manufacture of its products the company proposes to acquire the chemical plant and business of the Columbia Chemical Co. This latter company has a plant located at Barberton, Ohio, with a productive capacity of about 700 tons of heavy chemicals per day. Its principal products are soda ash and caustic soda, with lime fertilizer as its chief byproduct. The company also owns a fine limestone property near Zanesville which is being equipped and will be in operation in November.

Realizing the advisability and advantages in participating in the manufacturing and sale of kindred products such as window glass, art glass, paints, varnish and dry colors, the Pittsburgh Plate Glass Co. has also acquired controlling interest in the Patton-Pitcairn Co. and its subsidiaries, thereby securing a lasting commercial arrangement to participate in the production of these products. Consolidation arrangements have been approved unanimously by the boards of directors and it is expected that the plans will be ratified by the majority of stockholders in the near future.

Dye Bill to Be Pushed

Friends of the dyestuffs bill, which passed the House at the last session of Congress and now in amended form is at the head of the Senate calendar, have been busy during the recess of Congress securing pledges that this legislation will be pushed when Congress meets again in December.

On the other hand, it is recognized that the short session gives great advantage to such experienced opponents of the measure as are Senators Moses and Thomas. It was the Moses-Thomas opposition which prevented the bill coming to a vote at the last session. Since the appropriation bills and a vast amount of other legislation of first importance must be taken care of during the short session, there is a general disinclination to take up a matter which is certain to call forth protracted discussion. The opposition to the bill is non-partisan. Senator Moses is a Republican and Senator Thomas is a Democrat. The administration favors dyestuffs legislation. Most of the Democratic members favor such measures as may be necessary to safeguard the domestic dye industry.

W. R. Crane Sent to Tuscaloosa

W. R. Crane has been selected as the superintendent for the new experiment station of the Bureau of Mines at Tuscaloosa, Ala. Mr. Crane has been chief engineer for the War Minerals Relief Commission for the past year.

Two non-metallic specialists are to be assigned to the Tuscaloosa station. One is to be engineer whose duties will be confined to the laboratory. The other will be a field and contact man.

New C.W.S. Examination

Thirty Army officers have announced their intention to take the examination, late this month, for commissions in the Chemical Warfare Service.

Examinations will be conducted in November at which young men from civilian life with some chemical training may qualify as Second Lieutenants.

Chemical Warfare Officers' Reserve Corps

Tentative instructions governing appointments in the Chemical Warfare Officers' Reserve Corps have been issued as follows:

Recent legislation has made the Chemical Warfare Service a permanent branch of the Army, and a Chemical Warfare Officers' Reserve Corps is now being organized as per regulations from the Adjutant General's Department. The regulations governing reserve officers in the Chemical Warfare Service will be similar to the regulations governing reserve officers in the Army at large.

In a general way appointments will be made in the section for which the officer applies or for which his records show him best suited. For this reason a number of the applications of officers who have applied for the Chemical Warfare Service in the past will automatically be referred to the Chemical Warfare Service Board. The Adjutant General has ruled that all officers now holding commissions in any section of the Officers' Reserve Corps and whose records bear notation that they are qualified and were appointed for duty in some other section, now authorized (such as the Chemical Warfare Service), will be transferred to such section with their present grade and date of commission. Accordingly, officers now holding commissions in Engineers, Quartermasters, etc., bearing the notation Chemical Warfare Section will automatically be acted on by the C.W.S. Board. Even though this be more or less automatic, it is considered advisable that each one resubmit an application through the Adjutant General, Washington, D. C., for the Chemical Warfare Service Reserve.

Pending the promulgation of regulations governing appointments in the Officers' Reserve Corps under the provisions of the act of June 4, 1920, the following tentative instructions governing appointments are published for the information and guidance of all concerned:

WHO MAY BE APPOINTED

1. Persons who served as officers of the United States Army at any time between April 6, 1917, and June 30, 1919.
2. Former officers of the Regular Army.
3. Officers of the National Guard on June 4, 1920.
4. Reserve Officers' Training Corps graduates in accordance with Changes 6, S.R. No. 43, War Department, 1919.

GRADES IN WHICH APPOINTMENTS MAY BE MADE

1. Appointments will be made in the Chemical Warfare Service in all grades from Colonel to Second Lieutenant, inclusive.
2. A person eligible under these instructions may be appointed as a reserve officer in the highest grade which he held in the Army, or in any lower grade. National Guard officers found qualified, will be commissioned in the same grade as they held in the National Guard on June 4, 1920.

REQUISITE QUALIFICATIONS

Physical—(a) In the line of the Army, no defects disqualifying for hard field service; any minor defects to be waived. (b) In staff corps to have no defects disqualifying for particular kind of duty to be performed.

Professional—In general the records must show favorable recommendations, an average rating of at least 53, and suitability for appointment in the Reserve Corps.

Age—Appointees must be at the time of appointment between the ages of twenty-one and sixty years and no appointments in effect or hereafter made shall be terminated on account of age, but shall be permitted to continue in effect for statutory five years from date of appointment.

Citizenship—All appointees must be citizens of the United States or the Philippine Islands.

MISCELLANEOUS

Warrant officers and enlisted men of the Regular Army and National Guard may hold commissions in the Officers' Reserve Corps and continue their status as enlisted men.

A reserve officer may hold commission in the National Guard without affecting his reserve commission.

Employees of the Federal Government may not hold a commission in the Officers' Reserve Corps without the consent of the head of the department in which employed.

The President may order a Reserve Corps officer to active duty with any of the military forces of the United States at any time, for any period, *but except in time of national emergency expressly declared by Congress* no reserve officer shall be employed on active duty for more than fifteen days in any one calendar year without his consent. Mileage at the prescribed rate and compensation at the rate for the corresponding grade in the Regular Army will be paid while on active duty. There is no provision for pay while on inactive service status. A reserve officer is not entitled by law to retirement or retired pay. Reserve officers must provide their own uniforms and all articles of clothing and equipment which would be required in the public service. These articles may be purchased from the Quartermaster's Department at any time by reserve officers on the inactive list. Sales of subsistence and stores are not authorized. Any reserve officer may hold a commission in the National Guard without thereby vacating his reserve commission. Reserve officers may submit resignations from their commissions at any time, but the acceptance of same is at the discretion of the President. Notices of change of permanent address should be sent to the Adjutant General of the Army.

Expedition to Gather Scientific Data in South America

Dr. Henry H. Rusby, dean of the School of Pharmacy of Columbia University, is to start with a party composed of an ichthyologist, an entomologist, a motion picture photographer and possibly another physician for an extended exploration tour of the eastern slope of the Andes Mountains and the basin of the Vaupéz, Negro, Amazon and Madeira Rivers in South America.

This expedition has been formed to gather important scientific data on the flora and fauna of the region, with particular reference to their economic application as well as for their purely scientific value. Dr. Rusby has been in Washington in conference with heads of the various departments of entomology, ichthyology and plant industry, who will collaborate with him in interpreting the results of the data obtained by his party. An attempt will be made to introduce into our own tropical regions—the Philippine Islands—useful native tropical plants which may be discovered with the idea of increasing their usefulness. Dye, oil-producing food and medicinal plants will receive special attention both as to their sources of supply and their useful properties.

The problem of insects as carriers of disease and destroyers of plants will be carefully investigated in order to gather information to combat their ravages.

Dr. Rusby intends also to make a study of the various arrow poisons used by the natives of this region and thereby extend our limited knowledge of these toxic substances.

Personal

FREDERICK E. BREITHUT has accepted a position with the Calco Chemical Co., Bound Brook, N. J.

Colonel G. A. BURRELL has resigned his position as president of the Island Refining Corp. to take charge of refinery construction for the France-Canada Shipping Corp., 120 Broadway, New York City. He sailed for England on Oct. 23, to be gone three months.

C. C. COOPER, Editor *Mill Supplies*, Chicago; C. J. STARK, Editor *Iron Trade Review*, Cleveland, and RAY W. SHERMAN, of Class Journal Co., New York City, were elected respectively president, vice-president and secretary-treasurer of the National Conference of Business Paper Editors at the annual meeting in the Hotel Astor, New York, on Oct. 20 and 21.

Dr. W. D. ENGLE, professor of chemistry in the University of Denver, has been appointed acting chancellor of the institution on account of the illness of Chancellor H. A. Buchtel, who was recently stricken with paralysis.

Dr. COLIN G. FINK, of New York, recently addressed the Rochester Section of the American Chemical Society on "Modern Developments in Metallurgical Research."

H. D. FOSTER will work at the Bureau of Standards as research associate on problems connected with hollow clay tile. He has been appointed to this work by the Hollow Clay Tile Manufacturers' Association, under the form of co-operative agreement which is being used by the Bureau of Standards to carry on work of this sort.

A. J. GAILEY has left the W. L. Cummings Chemical Co., Lansdowne, Pa., to accept the position of research chemical engineer for the Electrometallurgical Co., Niagara Falls, N. Y.

Major E. HOLMES has recently been appointed manager of the chemistry department of the National Lime Association.

S. Z. KRUMM, graduate of the Colorado School of Mines and until recently instructor of metallurgy in that institution, has been appointed instructor in metallurgy and ore treatment at the Case School of Applied Science.

WILLIAM RUSSELL, the Dorr Co.'s London manager, is now in the United States on his regular annual visit to study the latest practices in the chemical and metallurgical fields.

RICHARD SHELDRIK has resigned as secretary, director and sales manager of the Kalbfleisch Corp., after a connection of fifteen years, and is now associated with D. A. Kimadi & Co., Inc., New York, as vice-president.

Captain WILKINSON STARK, late of the Army Ordnance Department, has joined the engineering staff of the John Johnson Co. Captain Stark was released by du Pont at the beginning of the war to supervise the design, installation and operation of the Army's caustic recovery and cotton purification, bleaching and drying divisions at Explosives Plant "C," Nitro, W. Va. Prior to the du Pont connection, where Captain Stark was in charge of similar work at the company's Hopewell Powder Works, he was for six years Assistant State Chemist of Missouri.

Dr. R. K. STRONG has recently been appointed head of the department of chemistry at Reed College, Portland, Ore., where special attention will be given to the chemical industries of the region, among them paper pulp, which promises to be the leading industry. Dr. Strong has made a careful study of the local situation during the last three years.

G. D. VAN ARSDALE will open an office in Los Angeles as consulting engineer, specializing in hydrometallurgy, flotation, etc. Mr. VAN ARSDALE has been for a number of years consulting chemist to the Phelps, Dodge Corp., with headquarters in New York, and is still retained by that corporation in the same capacity.

Obituary

CHARLES ERNEST ACKER, manufacturing chemist, died at his home, 80 Main St., Ossining, N. Y., on Oct. 18, in his fifty-second year. He built the plant of the Acker Process Co. at Niagara Falls, and was known as the originator of processes for the manufacture of tetrachloride of tin and carbon tetrachloride, and was the first to manufacture carbon tetrachloride in this country. Mr. Acker held about fifty patents in this and foreign countries for inventions relating to the chemical and electrochemical industries. Mr. Acker was graduated from Wabash College and Cornell University, and for several years was an electrical engineer in Chicago. He was a member of the American Institute of Electrical Engineers, Chemists' Club of New York City, the Society of Chemical Industry, Society of Arts (London), the Faraday Society (London) and other organizations.

JOSEPH J. MILLER, president of the Miller Chemical Engine Co., manufacturer of hand-operated fire extinguishers, died Oct. 12 at his home in Chicago, Ill., after an illness of seven months. Mr. Miller was born in Elizabeth, N. J., Sept. 16, 1848. He had been head of this firm in Chicago for many years.

ELISHA S. WILLIAMS, vice-president of the United States Rubber Co., New York, died on Oct. 8. Mr. Williams was born in Malden, Mass., in 1873, and was educated in the Malden public schools, taking a business course in the Malden high school. He then entered the employ of the Revere Rubber Co., of which he later became president. On Jan. 1, 1910, the Revere Rubber Co. was purchased by the United States Rubber Co. and he was then elected president of the Rubber Goods Mfg. Co. He was largely instrumental in the consolidation of the tire business of the Rubber Goods Mfg. Co.'s subsidiaries by forming the United States Tire Co. in 1911, of which he was the president until 1915. In 1915 he was elected vice-president of the United States Rubber Co., in charge of the mechanical goods business. He was also a director of the United States Rubber Co., a member of the operating council and president of several subsidiary companies.

Current Market Reports

The Iron and Steel Market

Pittsburgh, Oct. 22, 1920.

Cancellations, suspensions and postponements in the matter of steel contracts and deliveries continue, but are of diminished volume. Results of this movement are now plainly apparent in decreased operation at not a few of the steel mills. Naturally the mills affected are those that were charging the highest prices, and those that were charging the highest prices are those that had the smallest volume of business on books, for otherwise they would have been unable to promise the early deliveries for which particularly high prices were obtainable. Thus the mills that have the largest volume of cancellations and postponements are the ones that are least able to stand the operation, and accordingly their operations are promptly affected.

The fact should be noted, as having an important bearing upon the present steel market situation and the prospects for price changes, that the relative position of mills is quite different from that which usually obtains at a time when demand has greatly declined, but there remains, in the aggregate, a large volume of business on books. Ordinarily the mills are all sold for somewhat the same time ahead, since in an ordinary market prices are uniform among sellers. Since the first of the year there have been wide divergences in prices of different sellers, there having been for much of the time at least three markets. The

result is that some mills that were only recently the highest priced sellers are now the lowest priced among the independents. Again, the mills that are well sold ahead are disposed to maintain their prices and curtail their production to such extent as is necessary, while they fill the contract tonnage. Other mills are disposed to cut prices to the point at which they can book new business, for there is always a little business to be had, even in such a dull market as now prevails. No consistent and uniform policy, therefore, is likely to be adopted.

OUTPUT OF STEEL DECREASED

Production of steel has now been curtailed by so many mills that the rate of output is materially below that of August and September. Output of ingots as a whole in October, which will be reported upon in due course, will probably show a rate of something like 41,000,000 tons per annum, against a rate of about 42,700,000 tons in August and September. The Steel Corporation's rate of output has, if anything, increased somewhat.

A particularly interesting event of the week was that on Monday the Pittsburgh Crucible Steel Co. began quoting merchant steel bars at 2.35c., which is the Steel Corporation price. Previously the company had been confining its attention to the prompt market, in which it was able to secure very high prices. The action became known almost immediately to the other producers, who, however, showed no disposition to follow suit, but continued to quote from 3c. to 3.25c. Some of them have large contract tonnages, which would be more or less jeopardized if they reduced their prices, and the theory is that the company quoting 2.35c. will soon secure as much business as it requires, whereupon the price can be withdrawn.

Automobile and parts makers assert that they have secured some substantial price readjustments on steel contracts, but more adjustments are being sought. These trades are offering no new business of consequence as in the main they are fully bought, or more than bought, to the end of the year. Already they state that they expect to secure still lower prices when the time comes for them to place contracts for the first half of the new year.

FREIGHT CAR BUYING

The lightness of freight car buying, commonly attributed to inability of the railroads to finance loans upon suitable terms, should be better understood. In actual fact there is what amounts to a deadlock in the matter of prices. For a standard 50-ton open-top car the price at present is about \$3,400, while the railroads feel they ought to be able to buy at about \$2,700, for even that would be fully three times the lowest price before the war, and more than double the average price paid for all such cars that have been bought since the steel car came into vogue. In but very small part the extra price rests upon high prices for steel, and the car-building companies are not charged with endeavoring to make too large profits per car, but it is positively asserted that prices for the various trimmings and appurtenances which car builders buy as an assembling proposition are altogether too high. The Steel Corporation itself needs a number of cars, but is indisposed to encourage the present situation by buying cars. Certainly the corporation can have no objection to such part of the present price of freight cars as is based on the cost of steel, since the corporation would naturally furnish steel itself for any cars it should buy.

Rumors persist that the United States Steel Corporation will advance most or all of its finished steel prices by an average of say \$3 or \$4 a ton, the advance to be predicated upon increased costs due to the freight rate advances of Aug. 26. It seems certain that the corporation has formulated no definite policy in this matter, but undoubtedly the matter is being given careful consideration. Such slight advances might encourage the independents to drop, and thus the market would be equalized, something the independents should desire and should be willing to help bring about. Possibly the corporation will readjust its prices, instead of making a horizontal advance, so as to correct inequalities that may now exist.

There have been no further developments in basic iron

since the decline in the quotable market to \$42 valley reported a week ago. There has been no demand that would bring about any new condition. Foundry pig iron has been quiescent. Occasional small lots are sought by consumers from their regular sources of supply, and these have simply been sold at the \$47 valley price that the furnaces recently came to the conclusion could be regarded as "the market" until competition should effect a further reduction. In bessemer iron there is to be recorded a decline of \$1.50 a ton in the quotable market, a \$47 valley price becoming quotable by a large producing interest formally offering a lot of 1,000 tons at this figure. A sale of a carload at \$47 is reported.

As noted in last report, the declines in pig iron occur while coke is still at altogether irrational levels. Pig iron cannot find a secure and stable level as long as the cost of coke is so greatly in doubt. Connellsville furnace coke for spot shipment has declined \$2 in the past week, from \$17 to \$15 per net ton at ovens, but even \$15 is ten times the price in May, 1915. Until coal experiences the inevitable slump coke cannot get on a really proper level, as the coal used in making coke has too high a market value. The decline that has occurred in coke was brought about partly by the improved production of the past two or three weeks, but chiefly by the altered policy of a number of merchant furnacemen who, being in receipt of numerous requests for curtailment in shipment of pig iron against contracts, have concluded to bank or blow out in the near future, and to get ready for the event they either buy less spot coke in the open market or instruct coke operators to decrease shipments on contract. In some instances there are piles of coke at furnaces that are to be consumed before banking or blowing out.

The Chemical and Allied Industrial Markets

New York, Oct. 23, 1920.

The past week has shown no tendency toward improvement in the chemical market, in fact prices are uniformly descending, owing to the long deferred activity on the part of buying interests. Supplies are being accumulated on all sides and in practically every case stocks are in excess of the demand. On the other hand producers are confronted with the cost of production—which is steady, if not increasing—and have for the most part firmly maintained prices at the recent levels.

HEAVY CHEMICALS

Soda ash is firm at last week's figures of \$2.50 per cwt. for light ash and \$3 per cwt. for dense. Numerous rumors are abroad concerning producers' 1921 contract price, but so far nothing definite has been announced. The prophetic whisperings differ in matter of 10c. per cwt., \$1.85 being the favored mark. Very little business is being done in *aqua ammonia*, which is still quoted around 10½@11c. in carboys. Although prices as low as 12c. per lb. are heard for *carbon tetrachloride*, they are few and are concessions being made by second hands, but so far producers have firmly maintained the former 13@13½c. level. Concessions are also being made on *acetic acid*, glacial, 99½ per cent, and some business was transacted at \$11@11.50 per cwt., which is \$5 under the prices quoted by producers. Both *sodium nitrate* and *nitrite* dropped during the period, the former being now listed at \$3 compared with \$3.75@4 of the previous week, while the latter is down to 11@12c. in car lots against 12@14c., the prevailing price for some time. The prices of *tin* products have remained about the same with the usual routine business unaffected, *bichloride*, 50 per cent, being listed at 13½c. per lb. and *oxide* at 55@60c. per lb. by producers.

COAL-TAR PRODUCTS

Recent reports of this market have been consistently alike in summing up the business conditions. Dullness—implying absolute inactivity—has been the keynote for some time, and although prices on all items have been reduced to meet the slackness, buyers are firm in holding out for still lower levels; despite the fact that there have been no changes in the list, the trade is on the decline. The crudes on the

other hand show a healthy firmness as the supply is a little short of demand.

NAVAL STORES

It seems that the rock bottom has been reached in *rosin* prices, which is \$12.45 for all grades. The local demand has been fairly heavy when compared to the recent dullness, but foreign inquiry is practically nil and as a result considerable supplies are being accumulated in Savannah. *Turpentine* also declined during the early part of the week, but a slight flurry toward the end brought the quotation back to \$1.25 per gal.

OILS

Despite the low prices prevailing on *linseed* there has been no move on the part of buyers to take advantage of the present levels. Nominal quotations of \$1.07 have been received but the small amount of business that has been transacted is nearer the \$1 mark. *Cottonseed* remains at the 12@13c. price, and although there was a slight weakness exhibited in the early part of the period the closing market was firm. *Chinawood* dropped off 1c. and *coconut*, affected by *soya bean*, fell off slightly from 16½c. to 15½c. per lb.

The Baltimore Market

Baltimore, Md., Oct. 20, 1920.

The general waiting attitude on the part of buyers of fertilizer raw materials prevails on the local market. Offerings of all kinds are in evidence, but buyers are reluctant in expressing interest in them. It has been persistently rumored among the local trade that prices for spring on mixed goods are as follows: \$5.25 per unit of ammonia; 80c. per unit available phosphoric acid; \$2.50 per unit of potash. This price schedule has not been officially confirmed, but it seems to be the general belief that the finally accepted schedule will not be far out of line.

ACID PHOSPHATE

The market continues nominal at about \$18 per ton, basis 16 per cent, bulk, run of pile. Reports have been received, however, of sales as low as \$17. High-grade raw rock at the mines is being quoted nominally at about \$10 per ton.

NITRATE OF SODA

Chilean nitrate continues to come into this port on contracts, and relatively large tonnages are being placed in storage. Resales of spot lots have been made at \$3.15 per cwt. and the importers are quoting around \$3.20 per cwt. ex-vessel Baltimore and other Atlantic ports of arrival.

SULPHATE OF AMMONIA

There was reported a resale of sulphate this week at \$4.50 per cwt., basis 25 per cent. This makes a drop of 25c. per cwt. since last letter. Large stocks of this material are not in evidence.

POTASH

A price of \$1.60 per unit of K₂O has been the lowest offering noted for kainit and manure salts; in fact, very little of this grade of potash is changing hands at any price at this time. Nebraska producers have not yet offered their forward deliveries on the market, as most of them have contracted for their output up to November and in some cases up to the first of the year. Muriate of potash is being nominally quoted at \$2.20, although spot parcels are held 10@20c. higher. The lowest offering noted was a lot of foreign muriate at \$1.90 per unit c.i.f., North Atlantic port for November.

FISH SCRAP

Machine dried unground menhaden fish scrap is available at this writing at \$6 per unit of ammonia and 10c. per unit b.p.l. delivered Baltimore. Forward deliveries are being held at \$6.25 and 10c., and sales in a small way have been effected at this figure. The fishing on Chesapeake Bay has been very poor for the past week; in fact, the factories are now contemplating "cutting out" the latter part of this month or the early part of next, unless fishing improves materially within the next few days.

Alpha-naphthol, crude.....	lb. \$1.25 - \$1.45
Alpha-naphthol, refined.....	lb. 1.50 - 1.60
Alpha-naphthylamine.....	lb. 45 - 50
Aniline oil, drums extra.....	lb. 28 - 33
Aniline salts.....	lb. 33 - 36
Anthracene, 80% in drums (100 lb.).....	lb. 2.90 - 1.00
Benzaldehyde (f.f.o.).....	lb. 2.00 - 2.10
Benzalkline, base.....	lb. 1.35 - 1.40
Benzalkline sulphate.....	lb. 1.15 - 1.25
Benzoic acid, U. S. P.....	lb. 85 - 90
Benzoate of soda, U. S. P.....	lb. 80 - 90
Benzene, pure, water-white, in drums (100 gal.).....	gal. 35 - 40
Benzene, 90%, in drums (100 gal.).....	gal. 33 - 38½
Benzyl chloride, 95-97%, refined.....	lb. 35 - 40
Benzyl chloride, tech.....	lb. 25 - 35
Beta-naphthol benzoate (nominal).....	lb. 3.50 - 4.00
Beta-naphthol, sublimed (nominal).....	lb. 90 - 95
Beta-naphthol, tech (nominal).....	lb. 60 - 70
Beta-naphthylamine, sublimed.....	lb. 2.25 - 2.40
Creosol, U. S. P., in drums (100 lb.).....	lb. 18 - 19
Ortho-creosol, in drums (100 lb.).....	lb. 23 - 25
Creosylic acid, 97-99%, straw color, in drums.....	gal. 1.10 - 1.15
Creosylic acid, 95-97%, dark, in drums.....	gal. 1.05 - 1.10
Creosylic acid, 50%, first quality, drums.....	gal. 65 - 75
Dichlorobenzene.....	lb. 07 - 10
Diethylaniline.....	lb. 1.50 - 1.60
Dimethylaniline.....	lb. 90 - 1.00
Dinitrobenzene.....	lb. 30 - 37
Dinitrochlorobenzene.....	lb. 32 - 35
Dinitronaphthalene.....	lb. 45 - 55
Dinitrophenol.....	lb. 40 - 45
Dinitrotoluene.....	lb. 38 - 40
Dip oil, 25%, tar acids, car lots, in drums.....	gal. 38 - 40
Diphenylamine (nominal).....	lb. 80 - 85
H-acid (nominal).....	lb. 1.75 - 1.85
Meta-phenylenediamine.....	lb. 1.25 - 1.30
Monochlorobenzene.....	lb. 18 - 20
Monothylaniline.....	lb. 2.00 - 2.40
Naphthalene crushed, in bbls. (250 lb.).....	lb. 12 - 14
Naphthalene, flake.....	lb. 10½ - 11
Naphthalene, balls.....	lb. 12½ - 13
Naphthionic acid, crude.....	lb. 75 - 85
Nitrobenzene.....	lb. 14 - 19
Nitronaphthalene.....	lb. 40 - 50
Nitro-toluene.....	lb. 18 - 25
Ortho-amidophenol.....	lb. 3.25 - 4.25
Ortho-dichlorobenzene.....	lb. 15 - 20
Ortho-nitro-phenol.....	lb. 80 - 85
Ortho-nitro-toluene.....	lb. 25 - 40
Ortho-toluidine.....	lb. 35 - 38
Para-amidophenol, base.....	lb. 2.50 - 3.00
Para-amidophenol, HCl.....	lb. 2.50 - 3.00
Para-dichlorobenzene.....	lb. 08 - 12
Paranitroaniline.....	lb. 1.10 - 1.15

Para-nitrotoluene.....	lb. 1.25 - 1.40
Para-phenylenediamine.....	lb. 2.50 - 2.65
Para-toluidine.....	lb. 2.00 - 2.25
Phthalic anhydride.....	lb. 60 - 70
Phenol, U. S. P., drums (dest.), (240 lb.).....	lb. 12 - 20
Pyridine.....	gal. 2.00 - 3.50
Resorcinol, technical.....	lb. 4.25 - 4.50
Resorcinol, pure.....	lb. 6.25 - 6.75
Salicylic acid, tech., in bbls. (110 lb.).....	lb. 45 - 50
Salicylic acid, U. S. P.....	lb. 45 - 50
Salol.....	lb. 85 - 95
Solvent naphtha, water-white, in drums, 100 gal.....	gal. 30 - 35
Solvent naphtha, crude, heavy, in drums, 100 gal.....	gal. 20 - 26
Sulphanilic acid, crude.....	lb. 32 - 35
Toluidine.....	lb. 1.70 - 2.50
Toluidine, mixed.....	lb. 45 - 55
Toluene, in tank cars.....	gal. 35 - 40
Toluene, in drums.....	gal. 38½ - 40
Xylidines, drums, 100 gal.....	lb. 50 - 65
Xylene, pure, in drums.....	gal. 47½ - 50
Xylene, pure, in tank cars.....	gal. 45 - 50
Xylene, commercial, in drums, 100 gal.....	gal. 32½ - 35
Xylene, commercial, in tank cars.....	gal. 30 - 35

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark.....	lb. \$0.33 - \$0.38
Beeswax, refined, light.....	lb. 34 - 37
Beeswax, white pure.....	lb. 60 - 65
Carnauba, No. 1 (nominal).....	lb. 90 - 95
Carnauba, No. 2, regular (nominal).....	lb. 85 - 86
Carnauba, No. 3, North Country.....	lb. 35 - 36
Japan.....	lb. 18 - 20
Montan, crude.....	lb. 14 - 15
Paraffine waxes, crude match wax (white) 105-110 m.p.....	lb. 09 - 09½
Paraffine waxes, crude, scale 124-126 m.p.....	lb. 09½ - 10
Paraffine waxes, refined, 118-120 m.p.....	lb. 11 - 11½
Paraffine waxes, refined, 125 m.p.....	lb. 12½ - 13
Paraffine waxes, refined, 128-130 m.p.....	lb. 13 - 15
Paraffine waxes, refined, 133-135 m.p.....	lb. 16 - 17
Paraffine waxes, refined, 135-137 m.p.....	lb. 17½ - 18
Stearic acid, single pressed.....	lb. 20 - 21
Stearic acid, double pressed.....	lb. 22 - 23
Stearic acid, triple pressed.....	lb. 24 - 25

NOTE—Paraffine waxes very scarce.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940.....	gal. \$1.10
Pine oil, pure, dest. dist.....	gal. 1.50
Pine tar oil, ref., sp. gr. 1.025-1.035.....	gal. 48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank car f.o.b. Jacksonville, Fla.....	gal. 35
Pine tar oil, double ref., sp. gr. 0.965-0.990.....	gal. 85
Pine tar, ref., thin, sp. gr. 1.080-1.060.....	gal. 36
Turpentine, crude, sp. gr. 0.900-0.970.....	gal. 1.75
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990.....	gal. 35
Pinewood creosote, ref.....	gal. 52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.....	280 lb. \$12.45 - 15
Rosin E-I.....	280 lb. 12.45 - 15
Rosin K-N.....	280 lb. 12.45 - 15
Rosin W. G. W. W.....	280 lb. 12.45 - 15
Wood rosin, bbl.....	280 lb. 12.00 - 15
Spirits of turpentine.....	gal. 1.25 - 1.35
Wood turpentine, steam dist.....	gal. 1.22 - 1.35
Wood turpentine, dest. dist.....	gal. 1.18 - 1.35
Pine tar pitch, bbl.....	200 lb. 8.50 - 15.00
Tar, kiln burned, bbl (500 lb.).....	bbl. 14.50 - 15.00
Retort tar, bbl.....	500 lb. 15.00 - 15.50
Rosin oil, first run.....	gal. 72 - 75
Rosin oil, second run.....	gal. 75 - 78
Rosin oil, third run.....	gal. 92 - 95

Solvents

75-76 deg., steel bbls. (85 lb.).....	gal. \$0.40
70-72 deg., steel bbls. (85 lb.).....	gal. 38
68-70 deg., steel bbls. (85 lb.).....	gal. 37
V. M. and P. naphtha, steel bbls. (85 lb.).....	gal. 29

Crude Rubber

Para—Upriver fine.....	lb. \$0.26 - \$0.26½
Upriver coarse.....	lb. 17 - 18
Upriver caucho ball.....	lb. 17½ - 18½
Plantation—First latex crepe.....	lb. 25 - 28
Ribbed smoked sheets.....	lb. 24½ - 28
Brown crepe, thin, clean.....	lb. 22½ - 28
Amber crepe No. 1.....	lb. 22 - 28

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.....	lb. \$0.16½ - \$0.18
Castor oil, AA, in bbls.....	lb. 15 - 16
China wood oil, in bbls. (f.o.b. Pac. coast).....	lb. 17 - 17½
Cocoonut oil, Ceylon grade, in bbls.....	lb. 15½ - 16
Cocoonut oil, Ceylon grade, in bbls (nominal).....	lb. 17½ - 17½
Corn oil, crude, in bbls.....	lb. 12 - 13
Cottonseed oil, crude (f.o.b. mill).....	lb. 10½ - 11
Cottonseed oil, summer yellow.....	lb. 13 - 14
Cottonseed oil, winter yellow.....	lb. 13 - 14
Linseed oil, raw, car lots (domestic).....	gal. 1.07 - 1.08
Linseed oil, raw, tank cars (domestic).....	gal. 1.00 - 1.01
Linseed oil, boiled, car lots (domestic).....	gal. 1.09 - 1.10

Olive oil, commercial.....	gal.	3 00	—	3 50
Palm, Lagos.....	lb.	.103	—	.102
Palm, bright red.....	lb.	—	—	—
Palm, Niger.....	lb.	.091	—	.10
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.103	—	.123
Peanut oil, refined, in bbls.....	lb.	.12	—	.18
Rapeseed oil, refined in bbls.....	gal.	1 30	—	1 45
Rapeseed oil, blown, in bbls.....	gal.	1 60	—	1 70
Soya bean oil (Manchurian), in bbls, N. Y.....	lb.	.14	—	.141
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.10	—	.11

FISH

Light pressed Menhaden.....	gal.	\$0 80	—	\$0 90
Yellow bleached Menhaden.....	gal.	.83	—	.84
White bleached Menhaden.....	gal.	.86	—	.87
Blown Menhaden.....	gal.	.90	—	1.00

Miscellaneous Materials

All f. o. b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.	net ton	\$24 00	—	\$30 00
Barytes, ground, off color, f.o.b. Kings Creek	net ton	22 00	—	26 00
Barytes, crude, 88% to 94% ba., Kings Creek	net ton	10 00	—	12 00
Barytes, floated, f.o.b. St. Louis	net ton	26 50	—	28 00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The Connors Steel Co., Brown Marx Bldg., will build a 1-story, 77x400-ft. steel building for a steel mill, on 51st Pl. and Powell Ave. Estimated cost, \$50,000. Work will be done by day labor.

Colorado

LAFAYETTE—The Grand Valley Sugar Corp. plans to build a 600-ton mill. Equipment will be installed in same. Estimated cost, \$100,000.

STERLING—The Great Western Sugar Co., Sugar Bldg., Denver, will build a sugar factory to have a 1,200-ton capacity near here. Estimated cost, \$2,000,000. Work will be done by day labor.

Connecticut

NEW HAVEN—The Connecticut Adamant Plaster Co., River St., has awarded the contract for the construction of a 2-story, 120x160-ft. plaster factory to the Sperry Eng. Co., 82 Church St. Estimated cost, \$150,000. Noted Oct. 13.

Florida

LEESBURG—The Grass Fibre Pulp & Paper Corp. is building 3 paper pulp mills. Estimated cost, \$75,000. C. T. Logan, 1228 Crittenden, N. W., Washington, D. C., engr.

Illinois

EAST MOLINE—The Moline Pressed Steel Co. plans to build a 50x150-ft. enameling room and install an oven at its plant here.

Indiana

ANDERSON—The Lynch Glass Co. has awarded the contract for the construction of a 1-story, 50x120-ft. addition to its factory to the H. K. Ferguson Co., 6521 Euclid Ave., Cleveland, O. Estimated cost, \$60,000.

Iowa

GILMORE CITY—The city has awarded the contract for the construction of a sewage disposal plant to Phelps & Sons, Knoxville. Estimated cost, \$27,300.

Kansas

GALENA—The Eagle Picher Lead Co., Smelter Hill, Joplin, Mo., is having plans prepared for the construction of a 1-story smelter building on Miller St. here. Estimated cost, \$75,000. J. E. Webb, mgr.

Maine

FAIRFIELD—The Keyes Fibre Co., Waterville, has awarded the contract for the construction of a 1- and 2-story pulp mill to the Aberthaw Constr. Co., 27 School St., Boston, Mass. Estimated cost, \$125,000.

Maryland

BALTIMORE—A. Weiskittel & Son Co., 12th and Lombard Sts., plans to build a 1-story foundry, etc. Estimated cost, \$6,000.

Massachusetts

WESTFIELD—The Vitrified Wheel Co., Emery St., has awarded the contract for the construction of a 2-story, 15x100-ft. addition to its plant to F. J. Mahoney, 16 Orange St. Estimated cost, \$10,000. Noted Oct. 20.

Minnesota

AITKIN—The Bd. Educ. is having plans prepared for the construction of a 3-story high school. A chemical laboratory will be installed in same. Estimated cost, \$400,000. A. Casey, clk. K. T. Snyder, 738 Plymouth Bldg., Minneapolis, and H. Swanson, Crosby, enrs.

MINNEAPOLIS—The Bd. Educ. will receive bids about Nov. 25 for the construction of a 4-story, 220x300-ft. senior high school on 20th Ave., N. E. and Quincy St. A chemical and physical laboratory will be

installed in same. Estimated cost, \$700,000. E. Enger, 305 City Hall, archit. Noted July 20.

MINNEAPOLIS—The State Bd. of Control, Capitol, St. Paul, has awarded the general contract for the construction of a 3-story addition to the chemistry building on the State University Campus here to J. and W. A. Elliott, 906 Lumber Exch. Estimated cost, \$239,416. Noted July 28.

NORTHFIELD—Carleton College plans to build 11 college buildings to cost \$3,150,000. Plans include the construction of a chemistry building to cost \$300,000. D. J. Cowling, pres.

ST. PAUL—The city has received bids for 30,000 lb. liquid chlorine for treating city water in 100-lb. cylinders, from Noyes & Bros. & Butler, 6th and Sibley Sts., \$0.09 per lb., Electro Bleaching Gas Co., 18 East 41st St., New York City, \$0.0925 per lb., Hooker Electro Chemical Co., 25 Vine St., New York City, \$0.1089. Noted Oct. 5.

New Jersey

FLORENCE—The Florence Foundry Co. will soon award the contract for the construction of a 2-story, 50x100-ft. factory. Estimated cost, \$50,000. J. W. Levin, Liberty Bldg., Philadelphia, Pa., archit.

North Carolina

CANTON—The Champion Fibre Co. will build a 60x350-ft. pulp and paper mill. Work will be done by day labor.

North Dakota

HANKINSON—The city has awarded the contract for the construction of a sewer system to John O'Connor Co., Fargo. A septic tank and sludge bed will be installed in same. Estimated cost, \$82,000.

Ohio

CHAGRIN FALLS—The Adams Bag Co. has awarded the contract for the construction of a 1-story paper mill addition to the Myers-Kuhn Constr. Co., Metropolitan Bldg., Cleveland, O. Estimated cost, \$50,000. Noted Sept. 15.

CLEVELAND—The Atlas Fdry. Co., Shaw Ave., is having plans prepared for the construction of a 1-story, 50x100-ft. addition to its foundry on West 69th St. Estimated cost, \$40,000. J. E. Moore, 1900 Euclid Ave., archit. and engr.

Pennsylvania

FERNWOOD—The Eastern Fdry. & Machine Co., Ambler, has awarded the contract for the construction of a 1-story, 85x115-ft. manufacturing building here to C. R. Davis & Son, 15th and Ellsworth Sts., Philadelphia. Estimated cost, \$20,000.

PHILADELPHIA—The Sleigh Metallic Ink Co., 5907 Market St., has awarded the contract for altering the present 2-story building at 538 North 3d St. to the F. Mark Constr. Co., 2820 North 21st St. Estimated cost, \$10,000.

STATE COLLEGE—The Pennsylvania State College has awarded the contract for the construction of a 2-story, 60x160-ft. steel laboratory to the Austin Co., Bulletin Bldg., Philadelphia. Estimated cost, \$75,000.

South Carolina

UNION—The City Gas Co. plans to build a gas plant. Estimated cost, \$150,000. T. McNally, pres.

Tennessee

CHATTANOOGA—The Mutual Enamel Wks. Co. has awarded the contract for the construction of a foundry and plant to D. P. Robinson, 125 East 46th St., New York City. Estimated cost, \$800,000.

Wisconsin

DEPERE—St. Norberts College, Boyle Hall, is having plans prepared for the construction of a 3-story, 80x260-ft. science hall. A chemical laboratory will be installed in same. Estimated cost, \$400,000. W. E. Reynolds, 113 South Roosevelt St., Green Bay, archit.

KENOSHA—The Wisconsin Oxygen Hydrogen Co., Marion Ave. along the tracks

of the Chicago & Northwestern R.R., is building a 45x109-ft. building. Estimated cost, \$60,000. White, White, White & Co., 411-415 Pub. Serv. Bldg., archts.

MILWAUKEE—H. A. Poppert, 505 Cedar St., is in the market for brass foundry equipment, including blowers.

MILWAUKEE—The Shope Brick Co., 831 M. & M. Bldg., has awarded the contract for the construction of a 1-story, 90x115-ft. brick plant on State St., to the Amer. Contg. Co., 198 Milwaukee St. Estimated cost, \$25,000.

TOMAHAWK—The Tomahawk Pulp & Paper Co. is having plans prepared for the construction of several buildings to include a 50x231-ft. machine room, etc. V. E. Labbe, secy.

Wyoming

CASPER—The city plans an election on Nov. 2 to vote on \$250,000 bonds to construct sewers. Flushtanks will be installed in same. F. S. Knittle, City Engr.

Ontario

ALMONTE—The city engaged A. F. Macallum, engr., City Hall, Ottawa, to prepare plans and submit estimates for a waterworks system to include filters, reservoir, distribution system, etc. Estimated cost, \$263,695.

COOKSVILLE—The Shale Brick Co. of Canada, Crown Office Bldg., Toronto, plans to make repairs to present brick plant. Estimated cost, \$30,000.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1920 meeting Dec. 27, 1920, to Jan. 1, 1921, at Chicago, Ill.

AMERICAN ASSOCIATION OF ENGINEERS will hold a meeting on employment and education in the Congress Hotel, Chicago, on Nov. 12.

AMERICAN CERAMIC SOCIETY will hold its annual meeting the week of Feb. 21, 1921, at Columbus, Ohio, with headquarters at the Deschler Hotel.

AMERICAN ENGINEERING COUNCIL of the Federated American Engineering Societies will hold a meeting Nov. 18 and 19, 1920, in Washington, D. C. Headquarters will be at the New Willard Hotel.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its winter meeting at New Orleans, Dec. 6 to 9. Headquarters will be at the Hotel St. Charles.

AMERICAN MINING CONGRESS will hold its next convention in Denver Nov. 15 to 19.

AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS 1920 annual meeting will be held in the Engineering Societies' Building from Dec. 7 to 10 inclusive.

PHILADELPHIA SECTION, AMERICAN CHEMICAL SOCIETY, will hold its regular meeting Nov. 18 at the Engineers' Club, Philadelphia. Ellwood Hendrick will speak on "Relativity and Life."

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall national convention at Carnegie Music Hall, Pittsburgh, Pa., Nov. 10, 11 and 12.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: Nov. 5, Society of Chemical Industry; Nov. 19, American Chemical Society; Dec. 10, American Chemical Society, joint meeting with Society of Chemical Industry; American Electrochemical Society and Société de Chimie Industrielle; Jan. 7, American Chemical Society; Jan. 11, Society of Chemical Industry, Franklin Medal award; Feb. 11, American Electrochemical Society, joint meeting with Society of Chemical Industry, American Chemical Society and Société de Chimie Industrielle; March 11, American Chemical Society, Nichols Medal award; March 25, Society of Chemical Industry; April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry, and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Considerations on Dye Licensing

ACCORDING to our British contemporary *The Chemical Age*, the question of regulating dye imports in that country has had the benefit of wide discussion, and it resolves itself into four possible methods from which to choose. These are: First, free imports—which means no restriction, and this is generally regarded as inadmissible despite free trade traditions. National safety requires that there be a well-developed organic chemical industry at home. Secondly, protection by tariff is not feasible owing to the low value of marks, and because the German dye producers are past masters in getting around tariff restrictions. Thirdly, subsidy, which has been tried but has been discontinued. This always brings trouble in a democratic government. The fourth is the prohibition of dye imports except under license. This method will probably be adopted.

Now the calico printers have a very strong organization in England, and they speak with authority for their whole trade. They also appear to be in accord—which is more than we can say of American manufacturers. They would of course prefer free trade, so far as their own business is concerned, but they have declared themselves ready to accept the license system provided four stipulations which they make are agreed to. These are:

That the licensing committee shall consist of practical men with technical knowledge.

The color-consuming trade shall be consulted as to the licensing machinery employed.

The onus of proof as to the suitability of the British color to meet the needs of the trade must lie on the color maker and not on the color consumer.

The licensing system must be limited to a definite period.

What our British cousins mean by "a practical man with technical knowledge" would seem to be expressed in the words themselves, but over here the expression would need definition of the subject of technical training. Years of adherence to the rule of thumb in many industries have almost demanded of the practical man that he shall not even be familiar with the theory of his profession. We should be very much concerned if a commission to pass on the need of imports of dyes were made up of practical dyers of the type that has flourished for over a generation in a large number of dye houses and textile mills. They don't know enough of chemistry, both theoretical and applied, or of the materials to be considered, and besides this they have itching palms. The idea is sound to require men of technical training and experience, but it is equally important that they be men of character and under-

standing who are appointed to the posts. The records of more than a few practical dyers would disqualify them.

The second requirement that the color-consuming trade be consulted as to the licensing machinery employed may also work well in England, but here again we see trouble in America. The vindictive action during the last Congress of Senator MOSES of New Hampshire, for instance, who is likely to be returned to the Senate this year, in killing the dye bill with the jawbones of Senators THOMAS and KENYON, is significant. The influence of local corporations on some of our representatives in the House and in the Senate is unfortunate, but we must count on it. The present Mayor of Philadelphia, J. HAMPDEN MOORE, is another example who, while in Congress, was blinded to the country's welfare by the interests of one or two local mills. What such men think is not important, but the influence of German agents in the mill in their respective districts and the resolution of their directors to kill any American industry that stands in the way of cheapest dyes for their use are serious hazards. The act of CLAUDE KITCHIN while chairman of the Ways and Means Committee in Congress in discriminating against indigo and most vat dyes is another example. What Mr. KITCHIN thought was not important, but what the owners of some North Carolina mills thought was reflected in his deeds.

That the system of license be limited in the period of its duration is also fair. No industry is entitled to such permanent preference. The trouble is, however, that the duration of research cannot be predicted. We are still short of anthracene in the United States, and of vat dyes made from it, and while it would be unfair to give this situation an indefinite warrant for continuance, it would be doubly unfortunate to cut off protection too soon. The only hope seems to be in the synthesis of anthraquinone from some other intermediate than anthracene, because after the anthracene is extracted from tar the pitch seems unavailable for roofing or road making. The briquetting industry in which such pitch is available is not developed here.

The users of dyes are entitled to a voice in the matter. They are the interested parties, and they have the right, from the services they render, to very earnest consideration. But some users of dyes are in sore need to see a greater light. There is no reason at all why a large mill in New Hampshire should destroy the chance of the country to enjoy military protection, as one did in the last session of Congress. We are in full accord with the idea that the onus of proof of the need—or the lack of need—of a dye should rest on the color makers, but there must be provided a tribunal at once competent and impartial to render judgment. It would

be no less than a farce if the commission were to consist of agents of recalcitrant mills who are resolved to buy German dyes no matter what else happens, whether these men be in the Senate or in the House or otherwise appointed.

The textile industry in this country is a great institution. The point we want to make is that among them there are some who are too much interested in their own profits to consider national welfare. They should be set apart in a class by themselves, and participate only in separate hearings.

Extent and Duration Of "Readjustment"

A GREAT guessing contest is on—how far the "readjustment" in markets and in industries generally will extend, and how much time the operation will require. Predictions are numerous but usually lack definiteness. Then there are differences in viewpoint, or in the precise thing about which the prediction is made. Thus, in the iron and steel industry there are predictions that price declines will be over and buying will begin to revive by next April, while there are bankers who predict that the readjustment will require two or three years. The predictions do not refer to the same thing. The prediction in the steel trade is simply as to the next "buying movement" in steel products, while the banker is thinking of when it will be safe and profitable to make investments of the most permanent character, those that must depend on the long future for a return of the capital, with suitable earnings meanwhile. One case involves commodities that are to be bought and liquidated or consumed, the other involves property that must continue indefinitely to be worth its purchase price.

The comparison suggests that there are two distinct things. One, pertaining to commodity markets, is merely a market movement. The other, pertaining to the whole complicated relationship between property values, values of securities, interest rates and the value of the dollar generally, is in its essence a readjustment from war-time conditions and the strained conditions that curiously sprang into being upon the war's ending. By a free interpretation of the word "readjustment" it could be used to connote what occurs in a commodity market when that market rises or falls, but before the war the word was not commonly used in connection with market movements, and the meaning commonly attached to the word since the signing of the Armistice, translated into the vernacular, is in substance "getting over the war."

If we can "get over the war" in three years' more time, making five years in all, we shall do well enough. Meanwhile commodity markets will have their declines and advances at recurrent intervals according to the circumstances involved in the particular commodity, for some commodities have different wave lengths of fluctuation from others.

There is no reason at this time for anyone to fear readjustment, or to look upon the development as something that should not be welcomed. We must get over the war some time, and if the operation is delayed troubles will be piled up. That is what occurred after our Civil War. Either because our currency was fictitious, not being based on gold or any other definite thing, or because we were young, thoughtless and extravagant, we had a period of eight years of infla-

tion and reckless expansion that ended in a grand collapse, requiring five years of severe industrial depression to correct. That depression was the "readjustment" after the Civil War. We need have no fears regarding a readjustment after the World War that comes at this time, for we have builded too little rather than too much. We want industry and finance to get on a basis such as will make building wise, profitable and safe. The only danger is of the readjustment not being complete.

Already some far-sighted men have become hopeful that we are about to enter a new age in the history of American industry, an age that will be characterized by the absence of the industrial depressions that have marked our past and have been largely peculiar to the United States. The idea is that business will be conducted so conservatively that severe depressions will not be invited. These recurrent spells are natural to a young and growing country, so large a proportion of the "jobs" being in construction work that if building receives a chill the men thrown out of employment in the building trades cannot make work for themselves elsewhere.

Speculations on Sub-Atomic Energy

WE HAVE no less an authority than Professor A. S. EDDINGTON for the opinion that the source of a star's heat cannot be explained by the energy of gravitational attraction, but that it is rather to be accounted for by sub-atomic energy set free within the star. It is recorded in his address before the British Association for the Advancement of Science and published in the October number of *The Scientific Monthly*. Now the development of energy and the use of power from changes in state of sub-atomic particles is the substance of our hope for the continuance and development of civilization after the coal is gone, and it is also a proper basis for our fears for the future if the progress of research is too rapid.

Professor SODDY says, in effect, in "Science and Life" that if we could force the disintegration of radioactive substances so as to control the velocity of disintegration, we should obtain as much energy from one pound of such material as would be developed by burning 150 tons of coal, or that the same pound of material could be made to do the work of 150 tons of dynamite. We doubt if the world is quite ready for such efficiency as yet. Indeed, we offer this as an argument why we need development in the art of living and in human understanding and in character along with the study of science.

The same authority (SODDY) informs us that "Small as is the proportion of uranium and thorium in the rocks of the earth, the energy they evoke is estimated to be far more than the earth loses to outer space if the surface composition of the rocks is maintained uniformly throughout the core. Unless this is not the case, or unless the energy they evoke is being utilized in unknown ways, the conclusion follows that the interior of the globe must be getting hotter instead of colder. The uncomfortable prediction of the ultimate destruction of the world by fire is now at least as possible as the former fate pictured by science that the world must be steadily cooling and that it was only a matter of time before it became lifeless and dead."

The sub-atomic changes which Professor EDDINGTON

has in mind are not wholly atomic disintegrations. Normally we should say that energy is required for the synthesis of atoms, and is given off on their disintegration. But Professor EDDINGTON follows F. W. ASTON in his conclusion that all elements are constituted out of hydrogen bound together with electrons. By this hypothesis he says that "the nucleus of the helium atom is built up of four hydrogen atoms and two electrons," although the mass of the helium atom is less than the sum of the masses of the four hydrogen atoms which enter into it. But since mass cannot be annihilated, the deficit can represent only the mass of electrical energy set free in the transmutation. "We can therefore," he continues, "calculate the quantity of energy liberated when helium is made out of hydrogen. If 5 per cent of a star's mass consists originally of hydrogen atoms which are being gradually combined to form the more complex elements, the total heat liberated will more than suffice for our demands and we need look no further for the source of a star's energy."

This is contrary to our cheerful generalization in regard to the requirement of energy for atomic synthesis and its liberation when atoms disintegrate. Professor EDDINGTON admits that the synthesis of radioactive elements must be endothermic, although he claims that of helium to be exothermic. The rule would seem to work both ways or rather to be no rule at all in regard to the elements. But whether ASTON is right that all atoms are made up of hydrogen plus electrons, or HARKINS is right and they are composed of hydrogen and helium, or LANGMUIR is right and the electrons dance a quadrille in pairs and octets, or BOHR is right and they waltz forever, we have a present question in the integration or compounding of atoms just as we have in their disintegration. All authorities agree that in the presence of positive charges there exists a great, unknown code of behavior among electrons. They organize and arrange themselves under rules that are not yet clear, but in which the Quantum Theory may be involved. And electrons are not to be despised. They are very small, but only by comparison with atoms. In the picture of an atom, magnified to the diameter of a mile, which Dr. IRVING LANGMUIR described when he received the Nichols medal at the Chemists Club, the electrons had a diameter of five feet, whereas the nucleus was no bigger than a walnut.

That imaginary electron, five feet in diameter, is endowed with energy. Compared with the nucleus of the atom, which may contain anywhere from one to ninety-two positive charges, it is very big indeed. To call electrons atoms of electricity does not explain them. We might as well call them John or James or Warren Gamaliel. It is merely a name. They are replete with energy of an electro-negative character. And as for the nucleus or nut at the center, the electro-positive energy is still more concentrated.

We have no recognized aggregations of positive charges set free as positive electricity, but who shall say that there is no such thing? The single positive charges which Sir ERNEST RUTHERFORD drove out from an atmosphere of nitrogen which became first hydrogen ions, and then hydrogen atoms, may have come pretty close to being a positive electric discharge. Suppose, then, a vast number of such hydrogen ions should meet with a vast number of electrons, would anything happen? Might conditions be found under which the single positive charges would aggregate themselves into the

nuclei of more complex elements? If such conditions were brought about, what would happen to those of us who were conducting the operation? Should we undergo a transformation similar to that which would be brought about by the explosion of 150 tons of dynamite in our presence? Or would the passion of electrons when confronted with positive charges to organize themselves into pairs and octets, or whirling rings or whatever their habit is, demand, require and take so much energy as to reduce the temperature to -273 deg. C. and thus to repeat the legend—provided only we had a fair maid in the laboratory of The Sleeping Beauty? Or would it be hot infinitely beyond life or cold beyond death, according to the element produced?

A Suggestion To Western Chemists

AN INFLUENCE that will have an important effect upon the industrial development of the West is the success of the co-operative associations whose object is to obtain favorable economic conditions for the financing, handling and marketing of agricultural and other products. The California Associated Raisin Co. and the California Fruit Growers' Exchange, to mention but two, are nationally known through the extensive advertising of their products, "Sunmaid Raisins" and "Sun-Kissed Oranges." These and other co-operative associations are managed by keen business men, and it is not surprising to find that they have employed engineers and chemists to help solve some of their production problems, such as the drying of raisins and the utilization of byproducts. Thus the Exchange By-products Co., operated for the benefit of the citrus fruit growers, with a plant at Corona, Cal., is producing 3,000 pounds of citric acid daily, also lemon and orange oil, from cull fruit. Alcohol, edible oil and fuel have been made from the capstems and seeds of raisins. Such associations, the outgrowth of unity of interest, have brought about a degree of development, particularly in the utilization of byproducts, that could not otherwise have been attained. They have, therefore, effectively stimulated a co-operative spirit through the western section of the country.

This spirit has permeated the electrical industry—the power companies, the dealers, and, through the "self-interest" appeal, men in other lines of business—and all are co-operating in the problem of raising the seventy-five or more million dollars that will be needed yearly if development in the electrical industry is to keep pace with the demand that will be placed upon it. The future market for electric power has been accurately estimated through the co-operation of the power companies.

Industrial development in the West will be rapid during the next few years and there will necessarily be an increase in the consumption of chemical products. This demand, together with that which can be developed in the Orient, will be sufficient to create the beginnings of a well-rounded chemical industry on the Pacific Coast. Although the manufacturing chemist has, as a rule, been secretive and self-sufficient, it may be that the apparent advantages of co-operation in the agricultural and electrical industries will not escape the observation of Western chemical manufacturers; at least it is hoped that they will profit by the example set by the industries cited.

British Chemical Industry

FROM OUR LONDON CORRESPONDENT

London, Oct. 13, 1920.

WHILE the threat of a coal strike persists the condition of chemical markets and of the industry generally remains very unsettled. Buyers are still satisfying only their most pressing requirements and as a result prices show a general decline aggravated by increasing Continental and American competition and difficulties due to the exchange situation. On the other hand, business is certain to be brisk as soon as the depression has passed, as stocks are very low, and although the falling off in the textile markets is an adverse factor, good business, especially on export account, is expected by the end of the year.

SULPHUR AND SULPHATE FROM GYPSUM

The high price of sulphur has revived interest in the problem of utilizing the sulphur contained in British gypsum deposits and in those located in British colonies. It was reported shortly after the armistice that in Germany the Farbenfabriken Bayer had roasted gypsum with silica and powdered coal in a rotary cement kiln, passing the sulphur dioxide produced into its contact acid plant and utilizing the residue for the manufacture of cement. This process appears to have been abandoned owing to difficulties in the contact acid plant. On the other hand, Wride, in the *Chemical Age* (London) of Jan. 3, refers to various patents and a new process of making sulphate of ammonia by the interaction of gypsum with ammonia and carbon dioxide, and this process is likely to be tried on a semi-commercial scale in the near future. A third method of utilizing the gypsum is the manufacture of sulphuretted hydrogen gas via calcium sulphide and in this way it would be possible actually to manufacture sulphur at a low cost by burning the sulphuretted hydrogen in a Claus kiln or alternatively completing the combustion to sulphur dioxide and passing that gas into a chamber or contact plant. The cost of the coal or other fuel required in these processes is lower in many of the British colonies than in this country and such a process is therefore of greater importance in the colonies where the cost of American or other imported sulphur is increased by freight charges, and the development of the processes should therefore be of particular interest to American exporters.

"DIRECT" PROCESSES FOR SULPHATE OF AMMONIA

Sulphur economics are also reflected in the various processes which are being devised to utilize directly the sulphur and ammonia in coal and to eliminate the use of sulphuric acid as such in the manufacture of ammonium sulphate. In July, 1914, the writer had the opportunity of inspecting at the Gutehoffnungshütte one of the first Feld plants in which the crude coal gas was treated with ammonium polythionate with subsequent formation of sulphate of ammonia, free sulphur and sulphur dioxide, the latter being used again in a cyclic process. This plant had a capacity of two tons per day of sulphate of ammonia and the writer was greatly impressed at the time by the excellence of the chemical engineering work and the general efficiency shown by the designers. In spite of this, the Feld process seems to have proved too complicated in

practice, and the most likely successor is that now being worked out under the direction of Prof. J. W. Cobb, of Leeds University. A plant having a capacity of one ton of ammonium sulphate per day is now in operation, the process consisting in treating the coal gas with a solution of zinc sulphate to produce ammonium sulphate and zinc sulphide. The zinc sulphide is roasted and the sulphur dioxide used again to regenerate zinc sulphate from the zinc oxide obtained in a previous roasting. The sulphuretted hydrogen and ammonia in the coal gas are thus utilized, and it is understood that the process is now technically successful.

Other investigators are turning their attention to the manufacture of ammonium sulphite from gas liquor, and using sulphur dioxide gas obtained from spent oxide or any other convenient source. It has been found that under suitable conditions ammonium sulphite can be oxidized with reasonable rapidity to ammonium sulphate, the latter being present to the extent of over 90 per cent after a few days and the remainder of the ammonium sulphite being almost completely oxidized during storage. In this way the cost of manufacturing the sulphuric acid usually required is avoided, but in the case of a market so conservative as fertilizers considerable time must elapse before users can be expected to take up large quantities of a product containing small quantities of ammonium sulphite. This is not surprising in view of the fact that while in some quarters experiments have shown that ammonium sulphite is just as good a fertilizer as the sulphate, other experts have adhered to the opinion that the sulphite is to some extent a plant poison. It would seem that further work on this method should lead to valuable results and substantial economies.

AMALGAMATION OF TRADERS' ASSOCIATIONS

Reference has already been made in these notes to the rival organizations representing chemical merchants (see *CHEM. & MET. ENG.*, July 7, p. 33, and Aug. 4, p. 181). Under pressure of the Board of Trade, which was naturally disinclined to treat with more than one such body, it is now probable that the British Chemical Trade Association and the Chemical and Dyestuff Traders Association will be able to compose their differences and amalgamate into a completely representative body. Meanwhile the latter body has been doing good work by outspoken criticism of the forthcoming imports restriction bill, under which it is intended to allow dyestuffs to be imported only under license.

It is probable that there will be a long and bitter controversy on this and kindred matters when the bill is introduced into Parliament.

PROGRESS OF CHEMICAL INDUSTRY CLUB

The second annual dinner of the Chemical Industry Club is to be held at the Connaught Rooms on Nov. 19, and Sir William Pope is to take the chair on this occasion. Sir William Pope is the president of the Federal Council of Learned and Scientific Societies and that body has recently expressed sympathy with the objects of the club and three of the members of the council have been co-opted on to the club committee. The club now has 750 members and its future prospects are very bright. Reciprocal membership has been arranged with the Chemists' Club of New York.

The Chemistry of Cellulose and Its Compounds From the Colloidal Standpoint*

A Concise Descriptive Summary on Structure, Electrical and General Chemical Properties, Hydration, Oxycellulose—Action of Sulphuric Acid, Zinc Chloride, Ammoniacal Copper Oxide, Carbon Disulphide and Caustic Soda, Nitric Acid and Acetic Acid — Dope Solutions

By GUSTAVUS J. ESSELEN, JR.

CELLULOSE is one of the common materials of nature. It forms the structural basis of the vegetable world. If we consider the ultimate unit—that is, the cell—cellulose forms the cell wall, and is therefore to be distinguished from the rest of the plant, which is made up of the contents of these cells. It may be isolated in the laboratory by alternate treatments with chlorine and a weak alkali like sodium sulphite. The chlorine treatment decomposes the lignocellulose to water-soluble materials and the alkali hydrolyzes pectic bodies and dissolves the non-cellulose products from the preceding treatment.

STRUCTURE

The physical structure of cellulose varies widely, and a detailed discussion of this property is beyond the scope of this paper. In any consideration of cellulose, however, one should constantly keep in mind the fact that all its modifications have one common characteristic, viz., their colloidal character. It will be recalled that the two chief characteristics of colloidal substances are first, that they are heterogeneous, and second, that the ratio of surface to mass is a high one. As an example of the first of these, it may be noted that cotton fibers, when viewed under a microscope by polarized light, are seen to be physically non-homogeneous, and are of extremely fine structure.

As the typical cellulose and probably the purest form which occurs in nature, it is of interest to consider briefly the structure of the cotton fiber. These fibers, under the microscope, are seen to be flat, ribbon-like bands which are somewhat twisted and subjected to certain internal strains. These strains are probably longitudinal tensions which can be released by the action of solvents. Harrison, in the *Transactions* of the National Association of Cotton Manufacturers (1916), has pointed out that the cotton fiber is made up of four parts:

- (1) The outside membrane, which is not soluble in Schweitzer's reagent.
- (2) True cellulose.
- (3) Spiral fibers, all close to the outside membrane; these are not readily soluble in Schweitzer's reagent.
- (4) Insoluble matter occupying the core of the fiber.

It seems probable that those portions other than the main bulk of the fiber are cellulose in a different colloidal state. In other words, cotton fiber consists of a complex structure of cellulose in different physical states, and contains fatty, protein and mineral matter, partly in the central canal and partly dispersed through-

out the fibers. Cellulose from wood is a mixture of this typical cellulose with other celluloses less stable and less resistant to reagents.

ELECTRICAL PROPERTIES

When cellulose is immersed in water it assumes a negative charge. This probably is to be explained by the existence of a positive residual valency in the cellulose. As it is bombarded by hydrogen and hydroxyl ions the positive hydrogen ions are repelled, but the negative hydroxyl ions condense on the surface. These quickly rebound, but, as Langmuir has pointed out, owing to the fact that there is necessarily a time lag between the striking of the fiber and the rebounding, there is a higher concentration of these hydroxyl ions on the surface than in the main body of the liquid. In other words, hydroxyl ions are adsorbed. An illustration of this is seen in the fact that after a very dilute solution of sodium chloride is filtered through absorbent bleached cotton the filtrate is found to be a dilute solution of hydrochloric acid. In other words, the hydroxyl ions adsorbed on the cellulose have sufficient residual affinity to attract positive sodium ions from the solution and hold them in the vicinity of the cellulose fiber. A similar effect is observed when a very dilute sodium hydroxide solution is filtered through absorbent bleached cotton. In this case the filtrate is pure water. There will be frequent occasion to refer to these electrical properties in the explanation of the chemical behavior of cellulose.

GENERAL CHEMICAL PROPERTIES

Cellulose has the empirical composition $C_6H_{10}O_5$ and belongs, therefore, to the class of carbohydrates. Its molecular weight has never been determined, and accordingly the number of $C_6H_{10}O_5$ aggregates in a molecule is not known. The simplest point of view, as regards molecular weight, seems to be the modern one of Langmuir, which would regard the whole colloidal cellulose particle as a *colloid molecule*, consisting of large aggregates of atoms or group molecules held together by secondary valence.

The property of cellulose on which its greatest usefulness depends is its general chemical inertness. Modern theory explains this by the difficulty in making it take on or give up an electron. Under certain conditions, however, it does react, and then behaves like an amphoteric compound, exhibiting the property of a weak acid and a still weaker base. This behavior is generally explained on the ground of the mutual effect of the hydroxyl groups on the $-CO$ and $-CH_2$ groups which are not far removed in the molecule. In view of the general inertness of cellulose, an almost paradoxical

*A paper presented at the Seminar of A. D. Little, Inc., Cambridge, Mass.

behavior has recently been noted by Cross and Bevan, who showed by subsequent acetylation that two samples of cellulose, identical except for the fact that one had been boiled in distilled water for two hours and then dried, exhibited markedly different chemical characteristics. Besides this there is additional evidence pointing toward the conclusion that any treatment to which cellulose is subjected, either physical or chemical, modifies its chemical activity.

When treated with dilute aqueous acids or alkalis at room temperature, cellulose adsorbs the acid or alkali from the solution, accompanied by a very slight rise in temperature. It also readily adsorbs barium hydroxide from solution, as well as basic oxides from solutions of lead, zinc, copper, tin, aluminum, iron and chromium salts. The action of mineral acids at higher temperatures and concentrations will be taken up later under the heads of hydration and hydrolysis. The explanation of these varied chemical phenomena has already been referred to in the consideration of the electrical properties of cellulose. In this connection it is well to keep constantly in mind the fact that these electrical phenomena are exhibited at the surface, and are, accordingly, more pronounced in a colloidal material, such as cellulose.

HYDRATION

When cellulose is acted upon by acids a change occurs which is generally referred to as hydration. Its exact nature, however, has not been established. There are certain interesting experimental facts which may be noted before considering the theoretical aspects of the matter. It is a general phenomenon that when cellulose is treated with mineral acids the strength of the cellulose is greatly impaired. Very often, also, its affinity for basic dyes is greatly increased. For example, after treating with 1 per cent sulphuric or phosphoric acids and subsequent drying at 100 deg. C. for ten minutes, the treated portions develop a considerable affinity for methylene blue, which is a typical basic color. On the other hand, after the same treatment with hydrochloric acid, although the strength is considerably impaired, the affinity for basic dye is decreased. Accordingly the substance formed when cellulose is "tendered" by acid is not the same as the substance which causes an increased affinity for methylene blue. However, it has been experimentally demonstrated that this latter material is produced from the former by the further action of acids. The material having the affinity for basic colors is not oxycellulose, but a derivative of hydrocellulose. Harrison's opinion is that it is analogous to the material produced when cellulose is parchmentized and that it is a peptized form of cellulose—that is, a form in a higher degree of dispersion, which probably adsorbs substances of a sugar-like reducing character, formed by hydrolysis. The reducing power of these substances is usually considered to be dependent upon the latent activity of the $-CO$ group being brought into play.

On this basis, the increased affinity for basic colors is to be accounted for by the increased surface. The non-dyeing modification formed by hydrochloric acid is sometimes referred to as a dehydration product, but it seems more reasonable to explain it on the basis of peptization, with a possible resulting lessened adsorption of hydroxyl ions. It will be noted that this observation of the two forms of hydrocellulose casts some doubt on one of the methods of distinguishing between hydro-

cellulose and oxycellulose, inasmuch as the affinity for basic colors was always considered to be a characteristic of oxycellulose.

Hydration of cellulose is not limited to treatment with dilute acids, but is generally observed when cellulose remains in contact with water for any length of time, particularly if, at the same time, it is mechanically agitated. In the beater, in the process of paper making, hydration is accompanied by some hydrolysis, but the latter proceeds more slowly. Dr. Minor, of the Hamersley Manufacturing Co., has pointed out that there is a big difference between pulp which has been hydrated by long beating and pulp which has been brought to the same degree of hydration by a short beating, followed by cutting in the Jordan. In the former case there is plenty of chance for the production of mucilaginous substances by hydrolysis, the presence of which might account for the grease-proof properties of artificial parchment paper. Dr. Minor has further pointed out that there is botanical evidence for the formation of such mucilaginous substances by the hydrolysis of the cellulose.

A complete discussion of the many examples of hydration of cellulose would require a long paper devoted to nothing else. All that can be done here is to point out that hydration follows different courses, dependent upon the physical and chemical forces which are brought to bear upon it.

OXYCELLULOSE

The name oxycellulose is applied to all products formed by the action of oxidizing agents on cellulose. Oxycellulose is even formed by the action of light in air, together with acid substances, soluble in water, which have strong reducing power. Like hydrocellulose, oxycellulose is also produced in the beater in the process of paper making, the rate at which it is formed depending upon the rate at which fresh surfaces are exposed by the cutting of the fibers. Hydration, on the other hand, proceeds at a much slower rate.

Oxycellulose reduces Fehling's solution and readily adsorbs methylene blue. It may be considered as a peptized form of cellulose in which the adsorbed substances have greater reducing power than those present in hydrocellulose. In the formation of hydrocellulose the acid used converts part of the cellulose into a peptized state, part into a peptized state and hydrolyzes a part. This is entirely analogous to the action of acid on starch. One gets, therefore, compounds formed by the adsorption of hydrolyzation products by cellulose in different colloidal states. The reducing properties of hydrocellulose and oxycellulose are mainly due to the adsorbed products; the dyeing properties are due to the colloidal state of the true cellulose portion.

MERCERIZATION

When cellulose is treated with caustic soda solution, its degree of dispersion is increased in much the same manner that gelatine swells in water. As has already been pointed out, cellulose under these conditions adsorbs hydroxyl ions from the solution, forming adsorption compounds accompanied by changes in physical state at certain concentrations of alkali. Tolman and Stearn have suggested that the swelling is due to the repulsive force acting between the adsorbed ions, forcing the cell walls farther apart. At the same time the sodium ions are held in close

proximity to the adsorbed hydroxyl ions and thus form a second layer near the surface. As the swelling proceeds, the ions tend to arrange themselves in such a way as to neutralize the original electrostatic repulsion, and finally the swelling ceases to increase. It is conceivable that the environment might be so changed, as by the addition of salts, that the swelling might either decrease or increase still further.

At the same time that the swelling is taking place a decided shrinkage is noticeable, and also an untwisting of the fiber. The shrinkage is probably due to the strains to which reference has previously been made and which exist in the natural fiber. These become active when the fiber is softened. The untwisting is probably to be accounted for on the ground that the strains are distributed, partly at least, in spiral form.

Many colloidal substances react with iodine to give products of varied colors, the color combinations varying with the degree of dispersion. A low degree of dispersion gives a yellow color; as the degree of dispersion increases the color changes through orange, red, violet, to blue. By means of this test, mercerized cotton is shown to be cellulose in a more highly dispersed state than ordinary cellulose. This observation is checked by the ultra-microscope.

It is a well-known fact that cotton mercerized under tension develops a luster. A number of theories have been suggested to account for this luster, but it has now apparently been demonstrated that it is due to the smoothness of the surface of the fiber, as compared with the surface of cotton unmercerized, or mercerized without tension. Furthermore, cotton mercerized under tension possesses a regular structure, whereas the two others do not. Fibers mercerized without tension appear darker than unmercerized fibers, when both are dyed with the same percentage of dye, owing to the fact that the round section of a fiber mercerized without tension gives no internal reflection.

ACTION OF SULPHURIC ACID ON CELLULOSE

While the decomposition of cellulose by sulphuric acid has usually been referred to as a solution process, Dr. Minor has recently pointed out that it really is not solution but adsorption, followed by peptization and a subsequent entire alteration of atomic affinities. One of the earliest observations of the action of sulphuric acid on cellulose was in the manufacture of parchment paper. In this operation the first effect is the adsorption of sulphuric acid by the cellulose to form a series of adsorption compounds, accompanied by swelling and peptization. In making parchment this process is stopped by plunging the product into water, which decomposes the sulphuric acid adsorption compounds and gives a gelatinous hydrate. It is probable that whatever concentration of sulphuric acid is used a series of adsorption compounds is formed, accompanied by both hydration and hydrolysis, which result respectively in an increase of the reducing power of the cellulose and in molecular disintegration. If the aqueous solution of these adsorption compounds is boiled, glucose and sulphuric acid are produced. With less drastic treatment, however, it has been found possible to obtain a very considerable amount of molecular degradation without freeing the -CO groups. When wood cellulose is used, in which the -CO group is more reactive, the reaction with sulphuric acid is more complicated, and yields furfural and condensation products of the latter.

When cellulose is immersed in a concentrated aqueous solution of zinc chloride, swelling is also observed. In this case the swelling is due to the adsorption of zinc oxide. That zinc oxide is adsorbed is proved by the fact that, when precipitated in water, the resulting cellulose hydrate retains 18 to 25 per cent zinc oxide, which is removable only by acid. Dr. Minor has suggested that the adsorbed zinc oxide or zinc hydroxide weakens the bonds which hold the colloid cellulose molecule together. In other words, a certain peptization is accomplished. In confirmation of this theory, it may be noted that sodium hydroxide does not effect the solution of normal cellulose, but does dissolve cellulose hydrate precipitated from its solution in zinc or copper compounds. After the initial swelling in zinc chloride solution, gentle heat is required to bring about final solution. This also is regarded by Dr. Minor as confirmatory of her idea that it is necessary to break the bonds of the cellulose gel before solution is effected. If a hydrochloric acid solution of zinc chloride is used, the cellulose dissolves at room temperature, but the solution is then accompanied by a gradual molecular breakdown. The solution is a rather unstable one, being broken up by mere dilution with water.

SCHWEITZER'S REAGENT

When treated with an ammoniacal solution of copper oxide, cellulose is rapidly attacked in the cold, forming a series of gelatinous hydrates, which pass into solution. The action is again due to the initial adsorption of copper oxide, and the explanation is probably the same as in the case of zinc chloride. The solutions are not very stable, being readily precipitated by alcohol, sodium chloride or sugar.

If the cellulose is allowed to remain in contact with the cuprammonium solution for a long time, some oxycellulose is formed and also a considerable quantity of nitrite. In other words, oxidation takes place slowly. As regards hydrolysis, cotton cellulose is not hydrolyzed by the process, but some forms of cellulose are.

VISCOSE

There is a well-known reaction by which carbon disulphide reacts with alcoholic sodium hydroxide to yield a xanthate having the general formula $(XO)C : S(SNa)$, where X represents the hydrocarbon radical of an alcohol. Cellulose is enough of an alcohol to respond to this reaction. In carrying out the reaction in practice, cellulose is soaked in an aqueous sodium hydroxide solution of about 15 to 20 per cent strength for several hours. This is preferably done out of contact with the atmosphere to avoid oxycellulose formation. The surplus liquid is then removed in a centrifuge or press, the cellulose usually retaining about three times its weight of solution. It is then broken up into small pieces and treated with carbon disulphide in a closed container, the amount of carbon disulphide used being one-half the weight of the original cellulose. After standing several hours in a cool place, water is added to the mixture, and the solid is allowed to swell. On stirring, a smooth colloidal solution may be obtained which is yellow in color, due to the presence of colored by-products. It consists essentially of cellulose xanthate. The cellulose xanthate may be precipitated with alcohol or brine and redissolved in water. One or two such precipitations yield a product dissolving in water to a colorless solution.

From the standpoint of colloid chemistry, the process proceeds in several distinct steps. The initial treatment with caustic soda is similar to that which takes place on mercerization—that is, the cellulose adsorbs sodium hydroxide and swells, the swelling being accompanied by an increase in the degree of dispersion. The resulting hydration and increased surface renders the cellulose more reactive. Then the carbon disulphide is added and a metathetical reaction occurs. Cross and Bevan have shown that the best proportions of reagents are two molecules of sodium hydroxide and one of disulphide to each $C_6H_{10}O_5$ aggregate. The usual reaction between carbon disulphide and an alcoholic alkali requires only one molecule of the alkali, so that the second molecule of sodium hydroxide apparently necessary for the reaction must remain held to the cellulose by adsorption. The product is really, therefore, an alkali cellulose xanthate. Only one of the three hydroxyl groups of cellulose seems to be concerned in the reaction. After from twelve to twenty-four hours, Cross and Bevan have shown, the proportion of cellulose to xanthate radical corresponds to one xanthate radical to two $C_6H_{10}O_5$ aggregates, and this compound passes continuously to one in which there are four $C_6H_{10}O_5$ aggregates to each xanthate radical. This latter compound represents the material which spontaneously gels from a viscose solution, as will be explained below. It is, however, soluble in aqueous alkalis.

The solution of viscose is probably to be explained as a colloidal dispersion of the alkali cellulose xanthate in water. This dispersion is not stable; it breaks up again on standing at normal temperatures. This behavior gives an excellent example of hysteresis. The viscose first forms a continuous phase—or in other words gels—and then the gel shrinks symmetrically with exudation of solvent. The material possesses remarkable power to absorb water, as will be seen when it is pointed out that as little as 1 per cent viscose in solution will form a gel, and solutions containing 12 to 15 per cent no longer shrink spontaneously.

Viscose solution may be precipitated by alcohol or brine. If the precipitate is redissolved and again precipitated it is found that the percentage of Na_2O and sulphur in the compound gradually diminishes as the process is repeated, no break being observed in the curve between the original xanthate and the cellulose hydrate, which is the limiting product. Cross and Bevan explain this by saying that the size of the cellulose aggregate gradually increases—in other words, the degree of dispersion decreases. In view of our general knowledge of the behavior of colloidal materials in general and cellulose in particular it seems hardly reasonable to suppose that the cellulose molecule increases in size in the course of such treatment. It is a general property of colloid solutions that, with mechanical treatment, the size of the molecular aggregate decreases rather than increases. Furthermore, in the case of cellulose acetate and cellulose nitrate there is evidence that the molecule is gradually broken down by repeated solution and reprecipitation. Accordingly it seems more reasonable to assume that the degree of dispersion of the cellulose is increased in the case of viscose also and to look elsewhere for the explanation of the increased ratio of cellulose to carbon disulphide and alkali.

At first sight it might seem that it could be explained on the ground that we were dealing with an adsorption compound, but those who know most about viscose

state that there is very strong evidence that the combination is much stronger than that. The only way that a true chemical compound can be assumed, in view of the gradual change in composition, would be that the molecule was so large that the removal of one molecule of sodium hydroxide would effect such a small proportional change in the total amount present as to escape detection by the ordinary analytical methods. Since we do not find it reasonable to assume a decrease in the degree of dispersion, it seems that the most reasonable explanation is to assume a very large molecule from which the splitting off of one or two molecules of sodium hydroxide would not produce an appreciable percentage change. Such behavior would seem to find an explanation if it be assumed that the cellulose aggregate formed one large molecule which, because of its colloidal nature, presented a very large surface. It would contain a large number of $C_6H_{10}O_5$ aggregates and the molecules of sodium hydroxide to which these were connected could be gradually eliminated one by one or even in larger numbers at a time and still give us what appeared like an unbroken curve. This explanation avoids any necessity of considering a decrease in the degree of dispersion on the one hand, or any consideration of the compound as merely an adsorption one on the other hand.

Another way of coagulating viscose is by heat. When evaporated at a low temperature a solution of viscose gives a water-soluble residue. If heated to 80 or 90 deg. C. a viscose solution coagulates, and if dried at this temperature gives a residue which is not soluble in water. In either case an analysis indicates that more water is adsorbed by such residues than by the original cellulose. This seems to indicate an increase rather than a decrease in the degree of dispersion. That it really is an increase in the degree of dispersion is further indicated by the fact that the product dyes more readily, is more easily acetylated than normal cellulose and also adsorbs a larger amount of sodium hydroxide from solution.

CELLULOSE NITRATE

When cellulose is treated with concentrated nitric acid a true nitric acid ester is formed. Since the cellulose remains solid during the treatment, one of the factors determining the degree of nitration is the surface exposed. Probably the most common way of modifying the amount of surface is to add concentrated sulphuric acid, which is adsorbed by the fiber, and not only aids the reaction by increasing the degree of dispersion of the cellulose but also acts as a direct catalyst of the esterification. The highest nitrate known is the one containing three nitrate groups for each $C_6H_{10}O_5$ aggregate. This is usually referred to as the hexa-nitrate, and is the one used as an explosive. There seems to be an unbroken series of compounds with steadily but gradually decreasing amounts of combined nitric acid from this point down to hydrocellulose. As just mentioned, the compounds with the highest nitrogen content are among our best explosives. Those with an intermediate amount form the basis of the nitrocellulose plastic industry, while those with the lowest nitrogen have no particular commercial significance.

From the colloidal standpoint, the most interesting nitrates are those of an intermediate nitrogen content, which serve as raw material in the manufacture of celluloid. This industry affords as fine an example of applied colloid chemistry as there is to be found.

There are two general methods of making celluloid. In the first pyroxylin is combined with an alcoholic solution of camphor by working under heated rolls. A considerable amount of alcohol has to be used and the solvent loss is high. In the other method, which is the more usual American process, the moist pyroxylin is intimately ground with about one-quarter its weight of camphor. The water is then expelled by pressure and after the resulting cake has been broken up it is slowly sprayed with denatured alcohol and thoroughly stirred at the same time. Alcohol amounting to about 10 per cent of the weight of the pyroxylin is ordinarily used. The resulting mixture is allowed to stand for some hours to allow for proper impregnation by the alcohol and is then worked on warm rolls until translucent, when it is pressed into slabs and sheeted or given some other form. It is finally seasoned in driers at 50 deg. C. to remove any volatile solvent which may remain. From the colloid point of view, the finished product is a true colloidal gel.

ACTION OF ANTI-ACIDS IN CELLULOID

One of the difficulties of the celluloid industry is that there are present, unless great care is taken, unstable compounds formed during the nitration. These have a tendency to decompose and set free acid, which, in turn, tends to act catalytically to decompose the main body of the material. To counteract this tendency organic compounds of a basic nature are added. They usually have some slight solvent action on the nitro-cellulose, and therefore are presumably dispersed throughout the mass. As they are substances usually thought of as crystalloids it is possible that they may be present in a molecular degree of dispersion, although it seems more probable that they will be in a colloidal degree of dispersion.

Schwarz makes the statement that an anti-acid is the more effective the larger its particles are and the more colloidal its character. From our knowledge of colloid materials in general it would seem that his statement was contrary to the general conception, because the larger the particles the less the surface, and where, as in a gel, diffusion is slow the effectiveness of the anti-acid would have to depend upon the amount of surface exposed. In other words, in gels where the rate of diffusion is slow we have to depend much more on proximity for a chemical action than in true liquid solutions where diffusion is comparatively rapid and where mechanical agitation is readily possible.

Some basic organic materials have a tendency to crystallize in the gel. These, of course, would not be expected to be so effective as materials which remained in the colloidal or molecular state of dispersion. Contrary to Schwarz, it would seem more reasonable to expect an anti-acid to be more effective the finer its particles and the greater its degree of dispersion.

CELLULOSE ACETATE

An acetic acid ester of cellulose results when cellulose is treated with acetic anhydride in the presence of a catalyst such as zinc chloride, sulphuric acid, methylamine sulphate, etc. There are two general methods of producing cellulose acetate, both of which have a number of variations. One results in a fibrous cellulose acetate resembling in outward appearance the original cotton used as raw material; the other gives a granular product. Both have this in common, that the catalyst is adsorbed on the fiber and presumably facilitates the

reaction not only because of its true catalytic effect, as exhibited in any esterification, but also because it causes a swelling and probably an increase in the degree of dispersion of the cellulose. Very frequently, in practice, time is allowed for this adsorption of catalyst and resulting swelling before the acetic anhydride is added. That the degree of dispersion of the cellulose is really modified by the reaction is indicated by the fact that the longer the preliminary treatment the more rapid the reaction when the anhydride is added and the less viscous the solutions of the product.

In making the granular form of cellulose acetate, cellulose, usually in the form of cotton, is treated with a mixture of acetic acid, acetic anhydride and a suitable catalyst. The acetic acid acts merely as a carrier and takes no part in the reaction. As mentioned above, the catalyst dissolved in acetic acid is frequently mixed with the cellulose some time before the anhydride is added, although in other cases all are added together. Since cellulose acetate is soluble in acetic acid, the cellulose dissolves as the esterification proceeds. Samples are taken from time to time and when the desired solubility has been attained the reaction is stopped by adding an excess of water, which destroys any remaining anhydride and precipitates the cellulose acetate.

In the earlier processes the acetate thus formed was the tri-acetate, which corresponds to the hexa-nitrate. It later developed that, owing to their wider range of solubility, the acetates of most technical usefulness were those with a somewhat lower acetyl content than would correspond to a hexa-acetate on the C_{12} basis, but higher than would correspond to a tetra-acetate. These were at first prepared by adding small and carefully regulated amounts of water and sulphuric acid to the solution of cellulose acetate. As before, when the desired solubility was attained, the product was isolated by precipitation with water. While, outwardly, this secondary treatment is one of partial saponification, actually it is much more intimately connected with the colloid properties of the cellulose acetate. The reason for this is that an equivalent degree of saponification obtained by methods not involving the solution of the acetate does not give a product with the same wide range of solubilities. The effect may very possibly be connected with the opening up of the molecule in such a way as to make the $-CO$ group more reactive, because it results in a greatly increased solubility in acetone.

In preparing cellulose acetate in fibrous form it is given a preliminary treatment with sulphuric acid dissolved in glacial acetic acid, this step being similar to the one for preparing granular cellulose acetate. During this treatment the cellulose adsorbs sulphuric acid to such a degree that the amount adsorbed has to be taken into account in making up the bath for the following run. After removing the surplus preliminary bath in a centrifuge or press the cellulose is immersed in a mixture of acetic acid, acetic anhydride and some non-solvent hydrocarbon. The sulphuric acid catalyst, being adsorbed directly on the fiber, is in a particularly favorable position to hasten the reaction. While the proportion of non-solvent is so regulated that the cellulose acetate does not dissolve, the conversion is accompanied by a marked swelling and by a noticeable change in the index of refraction. When the product has reached the desired degree of solubility the surplus liquid is removed, usually in a centrifuge, and the residue is thoroughly washed with water. The product is cellulose

tri-acetate, and in order to render it soluble in acetone it is subjected to a partial saponification, as in the case of the granular form described above.

SOLUTIONS

When cellulose acetate is dissolved in an organic solvent a colloidal solution is obtained in which the cellulose compound is dispersed in the solvent in the form of a lyophile colloid. In common with all lyophile solutions, it is noticed that the viscosity of any given solution increases at a very much more rapid rate than the concentration of the solution. Furthermore, in common with all lyophile solutions, the viscosity of these solutions gradually decreases when they are subjected to mechanical treatment, such as shaking or pressing through capillary tubes.

This is sometimes explained as indicating a sort of structure even in the liquid and as being connected with liquid membranes which surround the colloidal particle. That it really also affects the substance which is in the dispersed phase is indicated by the fact that when a given sample of cellulose acetate is dissolved, which necessarily involves a certain amount of mechanical treatment in the way of stirring, and is then recovered from the solution in some manner, either by evaporating the solvent or by precipitation in a non-solvent and drying, the recovered cellulose acetates give solutions of a lower viscosity than solutions of similar concentration made from the original acetate.

Furthermore, in common with other lyophile colloids, cellulose acetate solutions show rapid changes in viscosity with variations in temperature, and the viscosity of the solution is influenced by its thermal history. It is very interesting to note that in making up lacquers or other solutions in which gums are included as well as a cellulose ester it makes a decided difference in the finished solution whether the cellulose ester is added to the solvent first or whether the gum is added before the cellulose ester. Sometimes the effect is so marked that if the gum is added to the solvent first the cellulose ester will not dissolve in the resulting mixture, but if the cellulose ester is added first the gum can be readily dissolved afterward. In other words, the cellulose ester is not soluble in the colloidal dispersion of the gum in the solvent, although the gum may be dispersed in the solution of cellulose ester. From this it would appear as if the cellulose ester and solvent formed the dispersion medium, and the gum the dispersed phase, and that it was not possible under the conditions cited to obtain a mixture in which the solvent, plus gum, was the dispersion medium with the cellulose ester as dispersed phase.

The colloid chemistry of cellulose acetate plastics is the same in its essential principles as that of celluloid, and accordingly need not be considered further at this point. It may be of interest, however, to consider briefly what happens when a solution of cellulose acetate evaporates, as for example in the drying of lacquer or airplane dope, or in the manufacture of continuous films such as are used for photographic purposes. In the simplest case the cellulose acetate is dispersed in the solvent. As this is spread out on a surface to dry the solvent gradually evaporates, and finally at a certain concentration a gel is formed—i.e., the dispersed phase and the dispersion medium both form continuous phases. The solvent continues to evaporate, until finally we reach a condition where the solvent becomes the dispersed

phase and the cellulose acetate the dispersion medium. This may very well be the situation in films which have become brittle.

If, on the other hand, we were to start with a cellulose ester solution containing, in addition to the cellulose ester and solvent, some material analogous to camphor which, though solid, was still a solvent of the cellulose ester, then on continued evaporation of the liquid solvent from the gel the solid and non-volatile solvent would still remain, and we would still have a true gel with two continuous phases, which presumably would not be brittle.

In selecting such a solid non-solvent it is desirable to select a material which is miscible with the cellulose ester over a wide range of proportions, for certain such materials are known which, although acting as camphor substitutes in certain concentrations, still, if these concentrations are materially increased, tend to form a crystalline deposit which, of course, renders the combination unfit for practical purposes.

Production of Gum Turpentine and Gum Rosin

The Bureau of Chemistry makes public the following figures showing the production of gum turpentine and gum rosin during the 1919-20 season by states. The unit for turpentine is the cask of 50 gal.; for rosin, the round or still barrel of approximately 500 lb. gross weight.

State	Turpentine Production, Casks	Per Cent	Rosin Production, Round bbl.	Per Cent
Alabama	38,100	10.4	126,000	10.2
Florida	136,900	37.4	457,500	37.0
Georgia	73,900	20.3	250,600	20.3
Louisiana	68,700	18.8	232,000	18.7
Mississippi	29,500	8.0	102,800	8.3
North Carolina	600	...	2,200	...
South Carolina	1,100	0.5	3,400	0.5
Texas	17,200	4.7	62,500	5.0
	366,000	100.0	1,237,000	100.0

The total production for the 1918-19 season was 341,000 casks of gum turpentine and 1,115,000 round barrels of gum rosin.

Watch Oil From Petroleum

The K. & J. Oil Co., of Canton, Ohio, has begun the manufacture of watch oil from crude petroleum of the Mecca field. The process was devised by Dr. C. F. Mabery, of Cleveland, Ohio, and affords a product which is said to be entirely satisfactory for chronometric lubrication. Hitherto watch oil has been prepared from the maxillary fat accumulations of the porpoise, and has sold for approximately \$250 per gal.

The Blast-Furnace Hearth*

A Wide Hearth Permits Steeper Bosh and Flatter Stack Lines With Many Resulting Economies. Especially for Smelting Mesaba Ores—Operating Data, Construction Details and Theoretical Considerations Point to Its Definite Superiority

• BY WALTHER MATHESIUS†

ON THE theory of the blast-furnace process and its chemical reactions our technical literature contains many able contributions, but little has been said for years about the scientific factors pertaining to furnace design. Perhaps the statement was made occasionally that a blast furnace must afford the opportunity for a uniformly intimate contact between the iron-bearing materials of the descending stock column and the furnace gases rising from the hearth. Just how this was to be accomplished, however, what specific features should be embodied in the furnace lines to attain this end, has so far been left almost entirely to the practical furnace man to find out. Thus blast-furnace design has to date been a rather exclusively empirical development. To the practical furnace operator belongs the credit for the accomplishments in this respect as obtained by departing from the older standards, to which the engineer, as a rule, was wont to cling.

However, with a number of examples in successful operation for a period of years, theory may now safely come to the front and demonstrate that its laws were violated in the past, or that the successful development is logical and correct, its accomplishment scientifically permissible. In this manner I shall attempt to show the development of larger furnace hearths to be a logical advancement of the art in its endeavor to design furnaces which will offer the least possible resistance to a rapid and uniformly regular descent of the stock, and which at the same time will permit the furnace gases to rise through this stock column with equally regular and uniform velocity and distribution.

HEARTH ORIGINALLY A RECEPTACLE FOR IRON

Going back in history, we find that the earliest types of blast furnaces, used in charcoal practice with cold blast, were built with comparatively small hearths. On furnaces with 8 or 9 ft. bosh diameter they seldom exceeded 3 ft. in width. It is apparent that the principal and probably only consideration determining the size of the hearth in those days was to provide sufficient storage space below the melting zone for the liquid products of the operation, so as to enable their withdrawal at convenient intervals. In view of the small output of these furnaces such hearth dimensions were apparently ample. Considering the slow rate of driving, the low blast pressures and small wind volumes used, the distance of the tuyeres from the furnace center and the resultant height and slope of bosh were evidently minor considerations. Thus it may be stated that in these early days the hearth dimensions had little or no effect on the working of the furnace proper

and, therefore, the design of the latter above the tuyeres was not influenced to any extent by the size of the hearth.

Since then, and right up to our own days, the size of the blast-furnace hearth has been very largely controlled by these same considerations of providing sufficient storage capacity for the molten iron and slag. With greatly increased productive capacity and faster driving on the one hand and steadily rising difficulties of raw materials on the other, the effect of small hearth diameters in conjunction with the resultant flat or high boshes on the working and economy of our furnaces became, however, more and more apparent. Yet tendencies toward radical departures from well-established standards were for years most effectively offset by the decided aversion of furnace men, well founded on sad experiences with "hearth trouble" in the form of breakouts, to store in their furnaces more than the necessary quantities of molten materials.

This conservative policy was strengthened through the quite popular assumption that gas distribution in the stack could be controlled by maintaining the proper "blast penetration" in the hearth, and that this was largely a question of selecting the proper length and size of tuyeres. Such belief and the failure connected therewith, of recognizing the condition of raw materials in the furnace, dependent upon method of charging and furnace lines, as the principal factor governing gas distribution, has only recently been dealt with by J. A. Mohr, in his paper presented before this Institute in May, 1919.

SUPPORT OF STOCK COLUMN BY BOSH

Lastly there remained the theory that a bosh with sufficient bearing surface was needed to properly support the stock column and to prevent the premature descent of the charges into the tuyere zone, thus avoiding compression and clogging there due to the weight to be carried. This supposition was, I think, definitely controverted by H. A. Brassert, in his paper read before this Institute in May, 1914, where he termed the furnace bosh of that day the chief impediment to a free travel of the stock. Since then it has been the basic idea governing the development of the large hearth, to design, with its aid, a furnace bosh of such steepness and so short as to avoid interference with the stock movement.

Why the evolution of such designs was naturally and logically linked with the desire to use higher percentages of fine Mesaba ores may readily be understood on the basis of the following theoretical considerations:

SHRINKAGE OF STOCK VOLUME

As long as the shrinkage of the stock volume taking place during its descent from the top of the bosh to the tuyeres is such as to result in a contraction of

the total bulk greater than the reduction of the furnace area prescribed by the bosh angle between the two points mentioned, we may assume that the furnace bosh does not impede the stock movement.

Such shrinkage of the stock volume may be due to one of two causes. The first of these, supposedly existent in every blast-furnace operation, is the gradual consumption, above the tuyeres, of the coke by the oxygen of the blast and such metallic oxides as may still be unreduced at this point. This shrinkage will, of course, be greater with a higher coke rate and will begin at an earlier stage, which means a higher furnace level, the farther the melting zone extends upward above the tuyeres. A flat or high bosh may, therefore, be expected to interfere with the stock movement, particularly on furnaces making low-silicon iron on a low coke rate. Attempts to use high blast heats, which, of course, would aim at a concentration of the melting zone, would no doubt aggravate matters under these conditions.

The second cause of shrinkage of the stock volume in the bosh is the gradual melting of the ore and the formation of slag, which enables the liquid particles to make their way into the furnace hearth ahead of the burning coke. It may readily be seen that this shrinkage can take place to an appreciable extent only in furnaces where all or a large part of the burden consists of lumpy material, which does not disintegrate in the furnace stack but retains its shape until it reaches the melting zone. Material of this character occupies, of course, a considerable part of the furnace volume and its melting in the bosh makes this volume available for other solid materials, especially coke.

If, on the other hand, all or a large part of the burden consists of fine materials, the voids existing in the coke charge will offer sufficient volume to receive

it, so that, as the stock column descends, the space occupied by ore and coke is practically no greater than that of the coke charge alone. Consequently the melting of the ore in the bosh cannot bring about any shrinkage of the stock column. Now modern Mesaba practice with high blast heats and low fuel rates will be seen, from this purely mechanical point of view, to present all of the above-mentioned conditions which tend to minimize the shrinkage of the stock in the bosh and to retard its beginning. Thus, Mesaba practice, more than other operations, was evidently in need of lower and steeper boshes, and practical experience has shown that their adoption has in every case resulted in improved quality of product, increased tonnage, lower fuel consumption and better use of hot blast temperatures, as stated and proved by James G. West, in his paper read before this Institute in May, 1918.

One of the incidental yet not negligible advantages of the larger hearth is its greater accessibility. With increased diameter, greater peripheral distances result for arranging feed and discharge pipes for cooling water, more working space is available around the tuyeres, blow stocks and the columns, as well as between the iron and cinder runners near the furnace, so that, on the whole, the cast-house work and also the mechanical maintenance becomes easier and simpler.

PRESENT HEARTH DIMENSIONS AT SOUTH CHICAGO

In order to illustrate the extent to which hearth dimensions have grown in recent years, I might mention that the average hearth diameter of all 22-ft. bosh furnaces at the South Chicago plant of the Illinois Steel Co. was increased from 16 ft. 6 in. in 1911 to 18 ft. 6 in. in 1919, and that the best average monthly production of these same furnaces equaled 512 tons per furnace-day in December, 1911, as against 556 tons in

May, 1920. For this increased output the adoption of larger hearths is primarily responsible, no enlargement of the furnaces or important changes of lines above the bosh having been made. During the same time our fuel conditions have developed no permanent improvement, but rather have experienced a decided change for the worse. The fuel consumption per ton of iron for the two periods cited above were 2,053 lb. in December, 1911, and 2,037 lb. in May, 1920.

In this connection I wish to point out that with this development of hearth dimensions the old practice of comparing furnace performances on the basis of their daily pig iron output per sq.ft. of hearth area is no longer applicable. It will readily be understood that this method of calculating furnace ratings, while capable of furnishing reasonably equitable data where hearth sizes bore the same relation to furnace dimensions as a whole, must naturally cease to be of value as soon as hearth diameters are increased beyond the customary proportion.

EFFECT ON STACK LINES

So far this discussion has dealt with changes of hearth and bosh dimensions which did not contemplate or entail any changes in the upper or stack part of the furnace. Lately, however, larger hearths have also enabled modifications of the stack lines which were not practicable before, although their desirability had been felt for some time. Particularly for operations where soft, easily reduced ores are used which are known to have a tendency to swell under the influence of the reducing furnace gases, the suggestion had been made that the uniform descent of the stock might be facilitated by increasing the batter of the stack lining, thereby reducing any "jamming" tendencies as well as friction. One way to obtain this would seem to require merely a decrease in the diameter of the stock line. This, however, did not appear to be permissible on

modern fast-driven furnaces using a large percentage of fine ores, since the gas velocity at the stock line, which, all other things being equal, must necessarily be determined by the available area, was known to be so high in many cases as to keep the surface of the charge in more or less constant agitation. Thus the limit would be closely approached beyond which dust losses would rapidly grow to excessive proportions. The diameter of the bosh, on the other hand, appeared to be definitely controlled by the limits of hearth dimensions and bosh angles. The only means remaining, then, of obtaining at least a slight increase in the stack batter was to carry the straight stock line section down lower into the furnace and thereby reserve the relief offered by a greater outward slope of the furnace walls for that part of the travel in which the swelling of the ore and consequently the friction was thought to be most prominent.

With the removal of the assumed limitations of hearth dimensions the situation has changed. Hearth diameters of 20 ft. and larger are in satisfactory operation and the opportunity is now here to increase the bosh diameter over the rather commonly accepted 22-ft. standard without sacrificing anything in suitability of bosh angle or height. The result to be expected from such designs should, of course, be a freer working of the furnace—that is, regular descent of the charges—and, other conditions being equal, a lower blast pressure.

OPERATING DETAILS NO. 6 FURNACE

Practical results appear to verify this theoretical analysis, since, for instance, No. 6 blast furnace at the South Works, of the Illinois Steel Co., which was designed along such lines of reasoning and has now been in operation for about two years, has consistently worked with a more regular and uniformly lower blast pressure than the other furnaces at this plant under

Average tons produced on linings of furnaces in blast Sept. 1, 1920 — 316,775.

comparative conditions. The principal dimensions of this furnace are given in Fig. 1, and data illustrating its performance are shown in Table I.

In order to afford a basis for comparison the average performance of all other South Works furnaces for the same period of time is given herewith in Table II. It should be noted that No. 6 furnace was operated for the entire period on practically 100 per cent Mesaba ores and that no scrap of any kind was charged. Beyond this the data presented are believed to require no special comment, except to point out that the fuel consumption was inferior to that of former years. This is due exclusively to the inadequacy, irregularity and inferior quality of our fuel supply. The fuel question, however, besides having been dwelt upon of late on several occasions, is not believed to be of primary interest in the scope of this paper; also, there appears to be little hope that further discussions by blast-furnace operators may produce beneficial results. Although the number of large furnace hearths installed throughout the country has increased by leaps and bounds during recent years, some furnace men are still maintaining a rather skeptical attitude and are occasionally voicing their objections with more or less substantial arguments. It may, therefore, be interesting to discuss here some of the points brought forth on the subject.

FIG. 1. PRINCIPAL DIMENSIONS OF FURNACE NO. 6, SOUTH WORKS, ILLINOIS STEEL CO.

REPUTED "JETTING" IN WIDE FURNACES

One of the most frequently heard assertions is that the large hearth furnaces must necessarily suffer from lack of penetration and that this ailment can be alleviated only by either considerably overblowing or by reducing the tuyere size to such small dimensions as to create a pronounced "jetting" action.

Advocates of this theory are, in my opinion, laboring under a wrong assumption with regard to the actual pressure drop through the tuyeres of a blast furnace. Calculations based on authoritative tests concerning the flow of air through orifices show that under average conditions of Mesaba practice this pressure drop is less than 10 per cent of the total blast pressure, and this figure has been repeatedly verified by taking pressure readings on furnaces in operation. Since it is also a scientific fact that the energy of the air flow through an orifice—that is, its ability to overcome resistance, or to penetrate—varies directly as the difference in pressure before and after the orifice,

it will be readily seen that, other things being equal, a doubling of the penetrating ability would require only a small increase in total blast pressure. However, practice on our largest hearth furnace in South Chicago has, I believe, conclusively demonstrated that no such additional penetrating energy is required. Based on an equal volume of wind blown, it was found best to use a slightly larger tuyere area than on other furnaces with smaller hearths. The only possible explanation for this seems to be that the materials are not packed as tightly in the large hearth and actually offer less resistance to the blast. The latter, therefore, with the same energy, is able to penetrate for a greater radial distance than was formerly possible.

TUYERE DIMENSIONS

Another point which has been raised as indicating the fallacy of the large hearth design is the fact that on many large hearth furnaces the tuyeres, extending from 9 to 12 in. into the furnace proper, are longer than those in use at other plants. The assertion has even been made that the "jetting" action as discussed before, together with the long tuyeres, produces "phantom" boshes, the actual working lines of the furnace having a much flatter bosh angle and smaller hearth than those provided in the design. I feel justified on the basis of our experience at South Chicago to say that we are able to use longer tuyeres to good advantage, and do so on furnaces with hearth diameters ranging from 17 ft. 8 in. to 20 ft. 9 in., largely on account of our steep and low boshes. Without these, shorter tuyeres would have to be used in an attempt to keep the bosh clean and prevent the formation of accumulations, the periodical building up and sliding off of which was formerly a source of continuous trouble at a good many plants. How the use of such short tuyeres in numerous instances resulted in "working too close to the bosh," cutting out the brickwork between the bosh cooling plates and leaving the latter sticking out into the furnace, is no doubt well known to many furnace men. A bosh in this condition becomes, of course, still harder to keep clean, as the erosion has produced a series of shelves which have justly been called "ideal lodging places for scaffold formations."

Troubles resulting therefrom have at times been charged to overcooling of the bosh, and warning notes have been voiced against the disadvantages of this evil. While I fully believe that overcooling is disadvantageous, I do not think that a decrease in the number of bosh plates used and a corresponding increase in the size of the unprotected areas between such plates is the proper remedy. We are using, at South Chicago, a closer spacing of bosh plates than is customary at many plants. With this construction we have eliminated to a large extent the above-mentioned shelf formation due to erosion, as well as the evils of overcooling, simply by not "working too close to the bosh." This we believe to have accomplished by the use of longer tuyeres.

We have had the opportunity of late to inspect during the repairing of several of our furnaces the bosh linings after successful campaigns and blowing out on account of business conditions. The evidence as found came up to our expectations. It was clearly apparent that all the cooling plates had been completely coated during the operation of the furnace; erosion was practically absent, so that the interior of the bosh presented a uniformly smooth surface which could offer little or no

resistance to the travel of the stock. The same inspections have in my opinion also furnished ample proof that the "phantom boshes" and "automatically reduced hearth dimensions" which have been theorized about do not exist in our furnaces. It has further been asserted that with an increase in hearth diameter it would be necessary to add to the number of tuyeres in order to avoid too great a distance between the same, since this would lead to the formation of pilasters of inactive material and an undesirable reduction of hearth area. In reply to this I can only state that on four of our furnaces at South Chicago, where the distance between the centers of adjoining tuyeres, measured on the periphery of the hearth, was 4 ft. 7½ in., 4 ft. 11½ in., 5 ft. 9½ in. and 5 ft. 10½ in., inspection after blowing out did not show any such formations. On our No. 6 furnace, where with 20 ft. 9 in. hearth diameter and ten tuyeres the distance between tuyeres amounts to 6 ft. 6½ in., we do not expect to have an opportunity for inspection for some time to come. I feel justified, however, in stating that the operation of this furnace does not reveal any indications of forming such accumulations between tuyeres.

WIDE HEARTH DEFINITELY SUPERIOR TO NARROW

Another statement which has been made in literature is that large hearths are not capable of maximum heat concentration and that for this reason a poor quality of fuel would here be more likely to give serious trouble through building up in the bottom than would be the case with smaller hearth dimensions. For the same reason large hearths were said to be not as well suited for the manufacture of foundry iron and other high-silicon grades. So far I have not been able to find a satisfactory explanation or theory as to how a small hearth favors maximum heat concentration, and am, therefore, unable to discuss this question.

As to the ability to operate under adverse conditions of raw materials I feel that little can be added to the statements made in Mr. West's paper and the discussions presented therewith before this Institute in May, 1918, except to say that furnace operations since have only furnished additional proof of the assertions made

on that occasion. The same is true regarding the question of manufacturing foundry iron, which at that time was fully covered by G. L. Collord.

In summing up these arguments I do not intend to deny that conditions may exist in this country—and they are well known to predominate abroad—where in normal operations furnaces with high or flat boshes and small hearth dimensions work entirely satisfactorily and compare well in results with those accomplished in Mesaba practice by furnaces with larger hearths. The fact remains, however, that in a great number of instances and under different conditions of raw materials, practice and products the larger hearth has been the means of obtaining improvements in output and economy which were not realized before.

Section A-A

Section B-B

FIG. 2. REINFORCED CONCRETE GIRDLE ENCLOSING FURNACE HEARTH

CONSTRUCTION DETAILS

Concerning the constructive features involved in the design of large furnace hearths it may be said that few departures have so far been made from former standards. On the contrary, it should be emphasized that the enlargement has not imposed additional or increased stresses and duties, while in some respects the demands upon the strength and wearing qualities of the construction have actually lessened. The volume for storing the molten iron and slag being larger, the maximum height to which these latter will rise above the low level prevailing at the end of the cast must for a given production necessarily be lower. Thus less pressure is exerted per sq.ft. of bottom and hearth walls, and there is less danger of metal reaching the level of the cinder notch or of slag interfering with the combustion of coke at the tuyere level. Such advantages are distinctly to the credit of the large hearth, as they could not have been obtained by increasing the vertical distances between the iron and cinder notches and the tuyere level. These dimensions must necessarily be kept below a well defined maximum, otherwise the metal bath, being removed too far from the zone of highest temperature, becomes the cause of producing physically cold iron, which is the source of many evils and worries in steel works as well as in blast-furnace practice.

Having made provisions for storing larger quantities

FIG. 3. CONVENTIONAL DESIGN OF HEARTH JACKET

of molten metal in the furnace and having reduced the number of casts per day accordingly, it becomes naturally of utmost importance to leave nothing undone toward minimizing the danger of iron breakouts. To obviate this most hated of all furnace troubles requires—aside from highest quality of building materials and first-class workmanship—uninterrupted, effective water-cooling and ample mechanical strength. The latter should preferably be pro-

vided in such a way that a possible failure of the former at any one point, with resultant local heating and perhaps an incipient breakout, will not at the same time reduce the strength of the mechanical bond. It is apparent that this might readily be the case where cast iron watercooled staves are placed immediately inside of a steel hearth jacket, or where watercooled hearth jacket sections are encircled by bands placed directly on the jacket itself. To eliminate this risk we have at South Chicago developed a design which has now been in use for several years and consists mainly of a circular beam of reinforced concrete placed at some distance from the watercooled cast iron hearth jacket, as shown in Fig. 2.

FIG. 5. CONVENTIONAL BOSH PLATE

4. REVISED DESIGN OF HEARTH JACKET

FIG. 6. REVISED DESIGN OF BOSH PLATE

The space between this concrete reinforcement and the hearth jacket is bricked up with firebrick, so that any radial pressure exerted on the hearth jacket, or expansion stresses of the latter, are directly transmitted to the concrete girdle. Provision is made by allowing clearance on the furnace side of each column so that no side thrust can be transmitted to them.

HEARTH JACKET AND BOSH PLATES

In order to reduce the chances of interruption in the watercooling of the hearth jacket segments, we have abandoned the rather conventional design as shown in Fig. 3, because it was found impossible at times to remove obstructions, carried in with the water, from the many bends and angles of the cast-in cooling pipes. In its place we are now installing the construction illustrated in Fig. 4. It will be seen that only simple hairpin loops of pipe are used in this design, so that in case of stoppage each pipe is accessible from the outside for practically its entire length. Also, should it be found impossible to remove an obstruction from one of the loops, it is no longer necessary, as before, to discontinue cooling the entire section.

Following similar lines of reasoning, we are replacing the bosh plate design as shown in Fig. 5 by that illustrated in Fig. 6. As may be seen, this type of plate is readily accessible for cleaning out, when required, by simply taking out the pipe plugs provided for this purpose. Accumulations of solid matter, which if per-

mitted to remain would interfere with the cooling effect and eventually lead to the destruction of such plates may readily be removed during operation. Furthermore, these plates have the advantage of a positively controlled flow of water, no core holes being required in the baffle plates such as are generally found in the older designs, where they permit of bypassing the water around the outside edge of the plate and of depositing solid matter in the remaining passages in which the flow of water is decreased correspondingly.

It should also be noted that in the new design the baffling of the plate is arranged parallel to instead of at right angles to the line of withdrawal from the brick-

work. Furnace operators who on account of adverse water conditions encounter the necessity of frequent bosh plate changes will appreciate this feature, as it effectively supports the arched surface and prevents indentations, which formerly interfered with the removal of the plates from the brickwork.

CONCLUSION

In conclusion I take pleasure in pointing out that the successful development of the large hearth blast furnace, unhampered, as far as I am aware, by any sacrifice of former advantages, is an exclusively American accomplishment, which today is evoking the keenest interest of our competitors abroad.

The results obtained so far justify the belief that permanent progress has been achieved to the lasting benefit of the American iron and steel industry.

Standardization of Sieves by the U. S. Bureau of Standards

During October the problem of standardization of sand sieves has been taken up by the Bureau of Standards with the object of preparing standard samples for their testing. The bureau at present maintains standard cement samples for checking 200-mesh sieves and these samples may be used for the determination of correction factors for such sieves, thus comparing them with the standards kept at the bureau.

The Manufacture of Lime for Chemical and Metallurgical Purposes*—II

✓ Description of the Applications of the Rotary Limekiln in Burning Stone and Recovering Spent Lime
—Advantages in Capacity, Low Labor and Operation Costs and
Utilization of Spalls†

• BY RICHARD K. MEADE

THE rotary kiln which has been so universally adopted for cement plants is now being employed to a growing extent for burning lime for chemical and metallurgical purposes. For burning lime to be so used it has many points of advantage over the shaft kiln, chief of which are the low labor and fuel cost of operating and the uniformity and thoroughness with which the lime may be burned.

There has always been considerable objection to the use of the rotary kiln for the production of building lime. This prejudice is to some degree due to ignorance on the part of the builder. Fine lime is generally the result of air slaking, and as air-slaked lime is partly reverted to the carbonate, it is natural that the builder should demand lime in lumps. The product obtained by the rotary kiln ranges in size from 2 in. to dust and is indeed often much finer than this. On being supplied with this fine lime, the builder supposes that it is air-slaked lime and refuses it.

At one or two plants producing rotary-kiln lime, the lime is hydrated and sold to builders in the form of hydrate. The hydrate made from this lime differs very little, if any, from that made from the ordinary grades of shaft-kiln lime.

Where the lime is desired for chemical and metallurgical purposes, such as in the manufacture of soda ash, wood pulp, carbide, cyanamide, calcium acetate, bleaching powder, bichromates, sugar, glass, ammonia, etc., for causticizing and furnace linings and flux—in short, where lump lime is not necessary—the rotary kiln will prove superior to the shaft kiln provided the quantity of lime justifies the outlay.

The first definite proposal to use a rotary kiln for burning lime appeared in a patent which was granted to Henry Mathey of New York in 1885 (U. S. Patent 330,603) on a process of making lime which consisted in first crushing the stone to a suitable degree of fineness to pass a No. 4 or No. 6 mesh screen, then burning in a revolving furnace which he invented (U. S. Patent 325,259). This consisted of a rotary cylinder somewhat similar to the present day kiln except that the center line of the kiln was horizontal, while the kiln itself was made slightly cone shape, this latter serving just as does the inclination of the straight cylinder to work the material through as the furnace revolved.

The John G. Jones patent (U. S. Patent 832,485), taken out in 1906, specifies the use of the present-day kiln, but covers the burning of lime in a "granular condition with granules of such size as will readily pass a 1-in. mesh screen," and this phrase occurs in all his claims. In view of the fact that the use of an apparatus

cannot be patented and that Mathey had previously suggested the burning of limestone in a granular condition, it is not at all surprising that Jones, so far as I know, has never made any serious attempt to sustain his patent.

Some experiments were also made in the early days of the cement industry on burning lime in rotary kilns. About 1905 the New York Lime Co. started to burn lime at Natural Bridge, N. Y., in a rotary kiln and shortly after this rotary limekiln plants were built by both the Union Carbide Co. and the Aluminum Ore Co. There are now in operation quite a number of rotary-kiln lime plants supplying lime for chemical and metallurgical purposes.

The Eastern Potash Co. is now installing at New Brunswick, N. J., a rotary-kiln lime plant equipped with ten rotary kilns, each 8 ft. x 125 ft. This plant when completed will have a capacity of 1,000 tons of lime per day and will be the largest lime plant in the world.

The Air Nitrates Works at Muscle Shoals, Ala., is also equipped with a rotary-kiln lime plant which contains seven kilns of the above size.

The Union Carbide Co. has two rotary-kiln lime plants and no other kiln compares with the rotary one for burning lime for carbide, because of the thoroughness with which this type of kiln burns the lime. Any unburned stone in lime for this purpose not only must be decomposed with a great expenditure of power in the electric furnace but the carbon dioxide liberated destroys the carbon electrodes.

The rotary kiln is now being quite extensively used also for burning dolomite for furnace lining. For this latter purpose much harder burning is necessary than can be obtained easily in a shaft kiln. The rotary kiln is also pretty generally used for calcining magnesite in California.

LIME RECOVERY

An application of rotary kilns for burning lime of particular interest in the chemical industry is the employment of these for burning lime from the waste carbonate of lime, or "lime sludge," obtained from the manufacture of caustic soda by the action of lime on soda ash and in sugar refining. Large quantities of this waste are produced by paper pulp mills, caustic soda works and beet sugar manufactories. The rotary kiln is now being employed for converting this waste into lime in all of these industries.

The attempt to burn the waste in a rotary kiln began about 1900, when the kiln was employed in connection with driers. This combination had already been tried on wet materials in the cement industry and proved a failure. The use of driers in recovering waste was soon abandoned and the employment of long kilns, following

*Read before the American Institute of Chemical Engineers, Montreal, June 28, 1920.

†For Part I see *CHEM. & MET. ENG.*, vol. 23, No. 17, Oct. 27, 1920, p. 841.

the cement practice on wet materials, was substituted. This, in connection with various schemes for thickening the waste sludge so as to reduce the water to be evaporated, has made the burning of lime waste commercially profitable.

The waste is usually received in the form of very thin sludge or slurry and it is necessary to dewater this by passing it through filter presses. The first presses employed were of the intermittent type. Recently, however, the continuous type presses have been found more satisfactory. The rotary presses are particularly convenient, as the cake may be scraped from the latter directly into the kiln. As fed to the kiln under these conditions, the material usually contains from 45 to 55 per cent water. It is desirable to reduce the quantity of water as far as possible in order to reduce the work of evaporating this water in the kiln.

Generally, producer gas is used for burning lime

carried from the press to the kiln on a belt conveyor. Recovered lime consists of small, slightly oval lumps ranging in size from that of a walnut down to dust. The color is slightly yellowish or greenish. The lumps slake quite a bit slower than rock lime and consequently causticize somewhat slower. On the other hand, the resulting precipitated carbonate of lime usually settles much more quickly. The lime will slake much more rapidly if the lumps are crushed before being added to the solutions to be causticized.

The lime will gradually pick up impurities from the process and also from the kiln lining, so that it is not possible to burn the same sludge over and over indefinitely. Instead of starting with an entire fresh lot of lime, therefore, it is the general practice to introduce a small quantity of rock lime into the system at regular intervals and to sell a corresponding amount of recovered lime or discard the equivalent amount of sludge. This loss is usually made up by adding ground

FIG. 6. COAL-FIRED ROTARY LIME PLANT

sludge. Where available and cheap, however, natural gas or fuel oil would be superior fuels. Pulverized coal is not entirely satisfactory, as the amount of ash introduced is considerable, due to the much greater quantity of fuel required to burn the wet sludge. The wet sludge in the upper part of the kiln serves to catch and retain a large part of the ash which in burning limestone would pass out of the stack.

The capacity of a rotary kiln burning alkali waste will vary very largely with the water content of the waste when fed to the kiln. If properly installed a kiln burning lime waste will have about 60 per cent of the capacity of the same kiln burning limestone—the actual amount depending to a large extent on how much water remains in the sludge.

The fuel requirements also vary with the amount of water in the sludge, but with a sludge containing 50 per cent water the amount of coal required per ton of lime will be from 800 to 1,000 lb. The amount of natural gas will range between 11,000 and 14,000 cu.ft., while the oil will range between 72 and 90 gal. The labor, power, repairs, etc., required to operate a lime-recovery plant will be about the same as are required to operate a plant burning limestone, with the addition of a man to watch the filter presses.

In many of the newer plants mechanical filters are a part of the causticizing equipment and the operation of these would be considered as part of the causticizing plant. If possible, these filters should be located so that they can feed the cake directly into the kiln, but where it is less convenient to do this the material can be

limestone to the kiln along with the lime sludge. The amount of lime necessary to replace losses usually amounts to about 5 to 10 per cent. The recovered lime, if burned at all skillfully, will contain as much caustic lime as the best lump lime made from limestone. Lime sludge usually contains a certain small amount of caustic soda and the reburned lime of course contains this soda which is so recovered, adding to the saving to be effected by the process.

The kiln used for recovering lime waste may also be used to burn lime from limestone provided the latter is crushed and there are suitable means at hand for feeding it to the kiln.

A lime-recovery plant will cost approximately \$1,500 per ton of lime recovered. This figure includes filter press, gas producer and buildings.

DESCRIPTION OF ROTARY KILN

The rotary kiln as used for burning lime does not differ in any particular from that used in the cement industry. It consists of an inclined cylinder from 6 to 8 ft. in diameter and from 60 to 125 ft. long. This cylinder is lined with firebrick and is supported on two or more steel tires which revolve on rollers. Power is received by means of a girt gear and supplied by a train of gears. The cylinder is slightly inclined from the horizontal, usually from $\frac{1}{4}$ to $\frac{1}{2}$ in. to the foot. The limestone is fed in at the upper end of the kiln and a jet of burning fuel is introduced at the lower. The limestone works its way through the furnace as the latter revolves and is burned by the gases passing

through the latter, falling out at the lower end of the kiln.¹

Fig. 6 illustrates a rotary-kiln lime plant. The stone is held in a large bin and is fed from this automatically and continuously into the kiln. The latter is heated in this case by pulverized coal. The lime falls out of the kiln into a cooler, which reduces its temperature to the point where it can be conveniently handled.

The capacity of various size kilns is given in the accompanying table.

CAPACITY OF ROTARY KILNS BURNING LIME FROM LIMESTONE

Diameter Unlined Shell, Ft.	Length of Shell, Ft.	Capacity per Day of 24 Hr., Tons	Approximate Horsepower Required*
5	60	18-20	4
6	60	25-30	
6	100	40-50	7½
7	80	55-60	10
7	100	70-80	12½
8	125	90-100	17

* NOTE—Motors should of course be larger, as this is actual average horsepower required.

SPALLS USED IN ROTARY KILN

The advantages of the rotary kiln begin with the quarry. With the old shaft kiln, whether of the most improved type or not, it is necessary to feed the kiln with stone of a certain size. If the stone is too big, the heat cannot penetrate to the center of the lump and consequently there will be a core or center of unburned limestone. If the stone is too small, the small pieces will work their way into the crevices between the larger stone and will choke the draft of the kiln, not only decreasing very materially the output of the latter but also causing irregular burning of the stone, due to the fact that the gases are forced to seek the path of least resistance and will probably avoid the central portion of the kiln in which the fine stone is more apt to lie.

As a general rule, the stone for the shaft kiln should be brought down to a size ranging between 2 and 8 in. Where the stone breaks up in the form of slabs, these latter can be quite long provided their least dimension is not greater than 8 in.

The necessity of having the stone of this size increases very materially not only the labor but also the waste in the quarry. Where the small stone or spalls can be sent to a crushing plant or other use can be found for them, the item of waste is not so great, but where they must be thrown away, the loss from this source is considerable. Quite a number of lime manufacturers have installed rotary kilns in connection with their vertical kilns with the express idea of burning up these small stones.

The saving of labor in the quarry is very considerable. The sledging of the stone to proper size and the hand sorting and forking add much to the cost of this. Anyone with experience in such matters will appreciate the fact that stone can be crushed to 2 in. by a stone crusher much more cheaply than it can be crushed to 8 in. by hand. "Cup grease" is much cheaper now than "elbow grease."

There are also numerous limestones which do not burn very satisfactorily in a shaft kiln owing to the fact that when the heat strikes them they decrepitate

and fall into small pieces. In some cases this action is very marked, the stone being almost reduced to dust. A very good example of this is the highly crystalline limestone found in the neighborhood of Franklin Furnace, N. J., some of the purest ledges of which have never been successfully burned in a shaft kiln due to this very action. Another limestone which is difficult to burn in a vertical kiln but which can be burned in a rotary kiln is the soft, chalky limestone of central Florida.

The saving effected in the quarry by a rotary kiln depends very largely on the size of the plant. If the plant is large enough, the fact that the quarrying can be done with steam shovels will appeal to even the layman as a great saving over the process of carefully breaking down all stone to proper size by means of sledges and then loading by hand on cars.

The earlier rotary-kiln plants nearly all reduced their stone to quite fine material—passing the 1-in. screen, or about ½ in. and under. In the writer's opinion this is unnecessary and good results are now being obtained with stone crushed to pass a 2-in. screen. This has the advantage of saving power and simplifying the outfit required.

The power required to crush the limestone may be safely figured at about 1½ hp.-hr. per ton of limestone crushed, which is equivalent to 2½ hp.-hr. per ton of lime produced (1.87 kw.-hr.).

In small plants which would naturally employ hand labor for quarrying, a small gyratory crusher with smooth concaves and head may be used, setting this to 2-in. screening and returning the oversize to the crusher for re-crushing.

As a general rule, better results can be obtained by screening out the dust from the coarse rock before burning. This increases somewhat the capacity of the kiln. This dust also contains a large part of the dirt which finds its way into the quarry, so that the writer has found its removal is of advantage in increasing the purity of the lime. In localities where water is abundant there would be no objection to washing the limestone to free it from dirt, as the wet stone would not affect materially the operation of the kiln.

Probably most chemical manufacturers will purchase their stone. In this event a good specification would be "to pass a screen with round perforations 2 in. in diameter and be retained on a screen with round perforations ½ in. in diameter."

Part III, dealing with Operation, will appear in a subsequent issue.

Search for Sodium Sulphate

Active prospecting for sodium sulphate has begun in the West and the Bureau of Mines is receiving numerous inquiries regarding its occurrence and its characteristics as found in nature. The bureau's chemists are at a loss to explain this sudden interest in sodium sulphate prospecting. Heretofore practically the entire supply has been the manufactured product, a considerable portion of which is a byproduct of hydrochloric acid making. Large deposits of sodium sulphate occur in Wyoming, Nevada and Utah—the "white alkali" of the semi-arid regions.

¹The construction of the kiln and its history and use in various industries was described in detail in the *Transactions of the American Institute of Chemical Engineers*, vol. 7, p. 153, and in the *Journal of Industrial and Engineering Chemistry* of September, 1914, p. 754.

²If the shaft kiln plant is large enough to justify the cost of the installation of very large crushers the steam shovel can be used here also and the limestone crushed in such crushers and sized by screens as is done by the Solvay Process Co. at Jamesville, N. Y. The waste in such a plant is large, however.

The Expansion of Glass at High Temperatures

BY W. B. PIETENPOL

THE problems met in the manufacture of optical and commercial glass have necessitated extended investigations concerning methods for determining the proper procedure and treatment of the glass during the productive stage. Relative to such research the solution of the means of determining a suitable annealing temperature is of importance depending upon the purpose for which the glass is to be used. In the manufacture of optical glass the greatest care must be exercised throughout every stage of the process in order that the glass may be homogeneous and free from strain.

Methods of determining the annealing range have been investigated by observing the disappearance of double refraction, the region of heat absorption and the rate of deformation of loaded rods. The relation of the rate of thermal expansion to the annealing temperature has also been pointed out, but without due emphasis upon the importance with which the determination of the rate of expansion bears upon the manufacture of glass. With a view of determining more definitely this relation and extending the temperature range through which the expansion of glass has been investigated, the author has carried out a series of experiments by a simpler and a more direct method than has heretofore been used.

To the engineer and industrial concern, laboratory results depending upon the measurement of minute quantities are not as acceptable as the results of experiments upon bodies comparable in dimensions with those found in the industries. Though acknowledging the refined laboratory technique of the physicist in measuring the change in dimensions of a centimeter of material in terms of the wave-length of light—i. e., of the order of one two-thousandths of a millimeter—in general there is some hesitancy in applying the results of such delicate measurements to the commercial process. This was considered sufficient reason for adopting a method by which the thermal expansion of relatively large samples of glass could be examined. The accuracy of measurement was thereby increased and the results not so dependent upon the homogeneity of the sample in question.

An electric furnace, 100 cm. in length and 6 cm. in diameter, was constructed with small openings about 12 cm. from the ends, through which specially designed microscopes were focused upon the samples of glass. The strips of glass were about 76 cm. long and rested upon a flat piece of asbestos rigidly supported within the furnace. By the use of auxiliary heating coils in parallel with resistances the temperature was kept uniform. As measured by thermocouples, the temperature in different parts of the furnace varied by less than 1 deg. C. during the observations. The microscopes were focused upon diamond scratches on the glass and upon small platinum particles resting upon the surface of the glass strip. By this means the temperature at which the glass began to soften could be very closely determined. The microscopes were supported upon a heavy steel frame which was kept at constant temperature during the observations.

The expansion of optical and other glass was measured from room temperature to 750 deg. C. The rate of expansion of annealed glass is nearly linear

until temperatures of 450 to 550 deg. C. depending upon the kind of glass. The rate of expansion then increases by four to six times through a temperature range of 60 to 100 deg. C. This is in agreement with the expansion determined by C. G. Peters of the Bureau of Standards by an interference method.

Measurements have been extended to higher temperatures. After the rapid increase in expansion the rate of expansion again becomes nearly linear, in general being slightly greater than at low temperatures. When the softening point is reached the rate of expansion gradually decreases and the length of the strip remains constant. At this point the glass loses its form and no linear expansion can be measured.

With unannealed glass the rate of expansion in general decreases from 50 to 150 deg. before the rapid ex-

THERMAL EXPANSION CURVES OF UNANNEALED LIGHT BARIUM CROWN, BUREAU OF STANDARDS, MELT 404

pansion takes place. This decreased rate may continue through a temperature range of 100 to 150 deg. depending upon the strain in the glass. In some instances the expansion through a range of 100 deg. is practically zero. Upon cooling, the strip of glass is shorter by a definite amount which is proportional to the strain which has been relieved. If the observations are carried to a sufficiently high temperature and the glass is slowly cooled, it becomes well annealed. A second set of measurements then taken upon the same strip of glass does not show this decrease in rate of expansion, but a nearly linear rate until the temperature of rapid expansion is reached.

This is shown graphically in the figure, which shows the thermal expansion curves of unannealed light barium crown, Bureau of Standards, Melt 404. The two curves referred to are marked 54-1st and 54-2nd. When an unannealed sample of the same melt of glass is heated to a point just below the temperature at which the rapid expansion begins (57-1st), the strain disappears entirely. The curve shows observations taken for about a hundred degrees upon cooling and the final point to which the strip of glass contracted at room temperature. Without moving the glass in the furnace, a second run was made with results as indicated by curve 57-2nd. The observations coincide with those of the previously indicated strip of annealed glass (54-2nd), showing that the annealing temperature had been reached. Curves 58-1st and 58-2nd show the results of heating the glass to a temperature below the annealing point. Thus a determination of the rate of thermal expansion may be used as a very exact method of finding the proper annealing temperature.

During the investigations which were made on the

thermal expansion of different kinds of glass, it was noted that a certain strip of glass underwent a rapid contraction soon after the rapid expansion took place. This occurred at a temperature above 620 deg. C., when the glass rested on asbestos board which had not previously been heated. Such asbestos contracts very greatly at high temperatures. This may have caused a compression in the glass sufficient to shorten the strip when in the plastic state.

What Constitutes Unfair Trade Practice?

BY AN INTERESTED OBSERVER

THE abstract of an address by William B. Colver of the Federal Trade Commission which appears in *CHEMICAL & METALLURGICAL ENGINEERING* of Aug. 4 (p. 191), coming at the time it did, presented an interesting coincidence, since Mr. Colver's speech gives the sanction of a member of the Federal Trade Commission to just such a line of investigation as that which Minerals Separation, Ltd., sought to exclude from the testimony of Theodore J. Hoover in the recent San Francisco hearing before the Federal Trade Commission.

Among those practices which Mr. Colver enumerates as being "unfair methods against competitors" is given "false claims to patents or misrepresenting the *scope* [*italics mine*] of patents. Statements of this character have been at times sufficiently broad to give claimant a monopoly of an industry."

Here is stated just such a case as Mr. Hoover perceives to be that of Minerals Separation, in its attempt so to construe its patents and so to broaden their claims as to bring within their scope the process of the porous bottom cell.

When Mr. Hoover learned from his reading of the testimony being given in patent litigations just what a broad monopoly Minerals Separation was attempting to establish before the United States court, and when he realized how absolutely at variance these present claims are from any conception of the process which one would gain from the reading of a manuscript treatise which had been written by two of the inventors shortly after the invention of the process and which had been handed by one of them to Mr. Hoover at the time he was manager of Minerals Separation, for his instruction as to the process, he felt it to be his duty to divulge these gross discrepancies of statement.

The fact of Mr. Hoover's possession of the manuscript was disclosed in an affidavit made by him in certain court proceedings in connection with the Miami infringement suit. The existence of the manuscript and the inconsistencies which it reveals had thus become public knowledge.

Three fellow engineers, to whom the question was submitted, recognizing, as they did, how absolutely convinced Mr. Hoover was that he had found in the conflicting statements as contained in the Sulman and Picard manuscript and the statements now made by Minerals Separation in prosecuting its infringement suits a palpable attempt upon its part to perpetrate a fraud upon the United States court, could have arrived at no other conclusion than that it was ethical, under the circumstances, for him to divulge the contents of

the manuscript. More than this, however, Mr. Hoover was himself impelled by the spirit of most enlightened ethics, in keeping with the modern trend of thought, in which the interest of the individual, as well as that of his employer, is subordinated to the general welfare. This idea is well illustrated in Article 3 of the code of ethics proposed by the American Society of Mechanical Engineers, which reads:

He should consider the protection of his client's or employer's interests in professional matters his essential obligation, *provided these interests do not conflict with the public welfare.* [*Italics mine.*] *CHEM. & MET. ENG.*, June 2, p. 1042.

This code, framed to conform to modern conceptions, was drawn up by eminent engineers from San Francisco, Minneapolis, Atlanta, Boston and Baltimore and may therefore well be presumed to express a broad spirit. In its preamble and the twelve articles of the code itself the underlying principle is enunciated that the benefit of the public must come first, that of the employer second, and that of the individual engineer last.

It was indeed by the spirit of this code that Mr. Hoover was actuated, that not only the interest of the mining public, but that of the whole United States should be considered before that of his former employer, or his own personal disinclination to enter into such a controversy.

"Misrepresenting the scope of patents," says Mr. Colver, is one of the "unfair methods against a competitor," statements of such a character as would give claimant "a monopoly."

Now this would certainly appear to be just what Minerals Separation is attempting in its efforts so to broaden the scope of the claims of its patents as to include within the agitation of these patents such agitation as is incident upon the introduction of the air through the porous bottom of the cell in the pneumatic process, an agitation which the U. S. Circuit Court of Appeals says, in its Miami decision, "is not even approximately of the violence and the duration of the agitation of the patent" (*E. and M. J.*, Dec. 1, 1917, p. 956).

We have, however, in this manuscript which Mr. Hoover has brought forward statements by two of the patentees of the process which show most conclusively what was the idea of these two inventors of the process as to the agitation of their process and just what it was that their discovery had added to the art, and that was simply the manner in which the "supersaturation" of the pulp was attained by a rapid rotary agitation of such violence that the gas [air] was "whipped into the ore pulp in minute bubbles."

This manuscript is particularly important because written at a time immediately following the invention, and because it was written in a purely scientific vein and was not influenced by any such spirit of mental reservation as that which subsequently led to the entire suppression of so purely scientific a treatise.

It was natural, under the circumstances, that in pressing the case before the Federal Trade Commission against Minerals Separation it was sought to introduce this manuscript, and also natural that Minerals Separation should "object" to its introduction as "incompetent, irrelevant and immaterial."

The arguments as to the introduction of this document and as to Mr. Hoover's interpretation of it are not of moment in this connection except in so far as

Minerals Separation objected to the introduction of the manuscript on the ground that it was improper for the Federal Trade Commission, as it was expressed, "to try out patent litigations."

Such an interpretation of the situation as this by Minerals Separation is simply a play upon words. The Federal Trade Commission was making no attempt whatever to try a patent case, but simply to establish such an attempted broadening of the patent claims as is shown by Mr. Colver to constitute objectionable practice, the establishment of which fact comes well within the province of the Federal Trade Commission.

That it is the duty of the Federal Trade Commission to determine whether among other improper practices, if there are such, Minerals Separation is also attempting improperly to enlarge the scope of its patents with a view to obtaining a monopoly is clearly pointed out by Mr. Colver in his speech.

If one turns to the pages of the Sulman-Picard manuscript treatise which were cited by Mr. Hoover in his testimony before the Federal Trade Commission in San Francisco, and compares statements found upon these pages with testimony presented by Minerals Separation in the United States courts, one may well believe that Mr. Hoover had every reason to feel himself impelled to disclose the suppressed manuscript.

Limited space precludes the quotation of more than two or three examples.

On page 6 of the manuscript, in a classified list of processes, we find this classification:

- (d) Dependent on the use of more or less minute quantities of oil to "cement" gas or air bubbles to the particles so covered with an indefinitely thin film of oil:
- Froment.
 - Sulman and Picard.
 - Sulman, Picard and Ballot.
 - Elmore (vacuum process).

On page 83 we find the following:

The second type of process, dependent on the flotation of oil particles by means of air or other gas, introduced in such a manner as to bring about a state of supersaturation in the solution, was discovered almost simultaneously by one of the authors in England and Mr. Froment in Italy, though published first by the latter.

In the Sulman, Picard and Ballot "frothing" process the same result is achieved without the employment of decomposable carbonates and acid or other gas-producing mixture; the necessary gas is supplied by means of air, which is whipped into the ore pulp in minute bubbles by means of rapid rotary agitation.

On page 94, referring to Froment and Minerals Separation "frothing" process, Sulman and Picard say:

Both these processes not only recover finely divided or slime sulphide mineral, but actually demand the presence of the same for the production of a coherent froth. The minute amount of oil added forms a film coating on the mineral which to all intents and purposes becomes part and parcel of the particle.

We have, on the other hand, the following as an illustration of Minerals Separation's interpretation of the Froment process, as presented in the United States District Court in Wilmington, Del., in which for their "thinnest possible layer" of an "ordinary oil" they chose an oil of such viscosity that it gave 13 per cent of oil upon the ore used, instead of an amount so small as to become "part and parcel of the particle," notwithstanding that Froment's instructions which had been given to Minerals Separation gave 1 per cent of oil as an example.

As to the resulting product of the Froment process,

Minerals Separation testified as follows (Miami Appeal Record, vol. 2, p. 1,455, Dr. Adolf Liebman's answer to question 472):

When you come to a scientific definition, we call froth air bubbles, collected on the surface of water or liquid. I should call the results as obtained in this way (Froment process) an emulsion, an emulsion produced by oil, some air bubbles, some mineral and some water. It may quite correctly be termed a magma, but a magma is not as definite as an emulsion. It is not a froth. When it comes to a strict definition it is not a froth.

These and many other statements, both as to the classification and description of their own and other processes, which are contained in the Sulman and Picard suppressed manuscript are found to be absolutely at variance with the entire contention of Minerals Separation in its litigation before the U. S. courts.

Moreover, the statements in the Sulman and Picard manuscript so evidently present the true knowledge and sincere convictions of these two inventors as to their own "frothing" process, as well as to the Froment and others, having been written down by them immediately following the invention, there would seem to be no question as to what any honorable engineer should do upon whom circumstances had thrust the knowledge of so monstrous a discrepancy.

Belgian Chemical Company Developments

A number of important developments and extensions in connection with the chemical and allied industries of Belgium, where, by the way, the process of reconstruction is proceeding more rapidly and infinitely more orderly than anywhere else in Europe, have to be recorded.

La Société Chimique de l'Escaut has been established, with headquarters in Brussels, to carry on the manufacture and sale of chemical products and also the sale of raw materials for use in chemical manufacture. The capital of the concern is 4,500,000 fr., the principal shareholders being La Société Anonyme des Verreries des Hamendes and La Société Anonyme Cuivres Métaux et Produits Chimiques d'Hemixen. Another new undertaking, the Belgoleum Compagnie Industrielle et Commerciale des Produits Oléagineux du Congo, has been registered at Brussels with a capital of 9,000,000 fr. At a meeting held in Brussels at the end of last month it was decided to increase the capital of the Société Générale des Produits Chimiques by the issue of new shares to the value of 6,500,000 fr.—*Chemical Trade Journal*.

Fuel of the Future

Prof. W. M. Thornton, in a presidential address to the Newcastle branch of the Institute of Junior Engineers, said that, with regard to heat, development must be looked for along the lines of new fuels. The coal age was passing, and the future of fuel was with the chemists. He referred to the possibility of tapping the earth's underground heat, and, turning to electricity and magnetism, said it was now known that all matter was made up of electrons, and the problem, at present barely conceivable, was to tap that source of electricity without going through the inefficient process of heat. The science of electrochemistry was gradually indicating lines of attack, and, if electricity could be obtained at high pressure from coal, oil or alcohol without burning, an immense advance would have been made.—*Chemical Trade Journal*.

New Deoxidizers for Steel Manufacture

Report of a Co-operative Investigation Sponsored by the National Research Council on the Function and Action of Deoxidizers, Together With Experimental Work to Find Low-Melting Mixtures of Scavenging Oxides

By J. R. CAIN*

A CO-OPERATIVE investigation was started in June, 1918, to select, according to a systematic procedure, some new experimental deoxidizing alloys for trial in steel manufacture. The original and primary motive was to contribute toward conservation of manganese in this industry, since manganese shortage was being experienced by American steel manufacturers at that time. This particular motive for the research became less urgent as time went on. Nevertheless, a knowledge of deoxidizers for steel manufacture which could, if necessary, contribute toward reducing the amount of manganese needed still seems of great importance. Many careful investigations made during the war showed that there is not available within the United States sufficient high-grade manganese ore for the needs of the steel industry, although there is a fair amount of ore suitable for making deoxidizers leaner than the 80 per cent ferromanganese which steel manufacturers prefer.

ACTION OF DEOXIDIZER

In order to give a proper perspective, it seems well first to consider briefly the mode of action of a steel deoxidizer, some of the problems which must be solved in a complete deoxidizer investigation, and, finally, some simplified investigations which could give most of the information needed by manufacturers and practical men, without requiring too great an expenditure of time and labor.

In general, a deoxidizer is added to steel to make the metal sound. In order to do this the following results have to be accomplished: Gaseous impurities must be eliminated or rendered incapable of causing blowholes and cavities; non-gaseous oxides must be reduced to metal, caused to separate as such from the bath, or made to combine with the deoxidizer or its reaction products to yield substances which can free themselves readily from the molten metal—i.e., presumably in fusible and fluid slags.

Considering somewhat more in detail the mode of action of the deoxidizer, it may be stated:

First, as to its effect on the gas content of the metal, there is little exact knowledge. In an empirical way it is known, for instance, that additions of ferro-silicon, ferromanganese or aluminum to molten steel before tapping remove the harmful effects of gases in causing blowholes. Just what happens to the gases—whether the deoxidizer combines with them and fluxes them off, whether they are given off as gas wholly or in part, or whether addition of the deoxidizer merely enables the metal to hold more gas in solution—these are important questions not yet adequately answered.

Second, considering a deoxidizer (ferro-alloy) with two or more reactive constituents (e.g., Mn: C, Al: Si,

Mn: Ti, Mn: Si: Ti alloys, the iron in the ferro-alloy being regarded as inert) in respect to its chemical action on solid oxide impurities in carbon steel, the following cases may arise:

a. The active elements in the deoxidizer may, and probably will, be consumed at unequal rates in reacting with the impurities—e.g., aluminum, being more reactive than manganese, may be consumed faster, hence

b. The deoxidation slags produced by such differential consumption of the deoxidizing element will vary correspondingly, and, in general, will be different for each different alloy of the same active elements.

c. For any given impurity a condition may be reached such that when the impurity has entirely consumed one of the active elements in the deoxidizer, there is no further action on what remains of the other active elements; these may then alloy with the steel.

d. The reaction products (deoxidation slags) will tend to free themselves from the metal bath in proportion to their fusibility, fluidity and insolubility in the molten metal, and in general these properties of the products will be different for each combination of deoxidizing elements.

e. The deoxidizer may not reduce or flux off completely the foreign oxides, some of which may remain in the bath.

f. Usually the deoxidation period is too short for the establishment of equilibrium in the physicochemical sense of the word.

Third, considering the deoxidizer in relation to its possible action on carbides, phosphides and sulphides, it can be seen that for each of these there are the same possibilities as for oxide impurities. It can also be seen that the deoxidizer may, and probably will, react to some extent with all classes of non-gaseous impurities at the same time, and that, accordingly, extremely complex chemical reactions may take place.

Fourth, considering the action of the deoxidizer with respect to variables of a physical nature as contrasted with the chemical variables heretofore discussed, it is evident that the mode of action of each deoxidizer and the resulting deoxidation products will be affected by such factors among others as:

a. Temperature of the molten steel.

b. The manner of adding the deoxidizer—whether molten or solid.

c. The amount of the deoxidizer added.

d. The time allowed for action of the deoxidizer.

e. The use of two or more deoxidizers successively added.

f. The concentration of the active element in the deoxidizer.

To summarize, it would seem that there is small possibility of obtaining with any reasonable expenditure of effort or time accurate and complete information concerning each individual deoxidizer in respect even

*Bureau of Standards, Washington, D. C.

of the few variables which have been mentioned. Consequently, it is necessary to consider various experimental short-cuts that will approximate to a complete solution.

VALUE OF INFORMATION ON FUSIBILITY

Conforming to this idea, it was suggested by Dr. H. M. Howe that one of the most important functions of the steel deoxidizer is removal of the solid oxides contaminating the molten metal, which removal is usually believed to be accomplished by the formation of deoxidation slags which fuse and float to the surface of the metal and are usually skimmed off or poured off before tapping. Accordingly, the most fusible deoxidation slags are the most desirable ones, and a simple way to select new deoxidizers would be to choose such alloys of the active deoxidizing chemical elements as would yield very fusible combinations of the oxides of these elements. Such fusible combinations of oxides could be found by experimentally determining the melting points of a series of mixtures of the oxides. Once the most fusible oxide combinations were found experimentally by such procedure the calculation of the composition of the corresponding deoxidizing alloy is simple.

It is recognized, of course, that this view of the mode of action of the deoxidizer is a simplified one, and that it leaves out of consideration many of the factors of possible or known influence. However, this investigation constitutes but the first phase of a more extended research which has been begun at the Bureau of Standards consisting of the following parts:

1. A systematic selection of some new deoxidizing alloys—the present investigation.
2. The selection or production of the most practicable of these alloys to manufacture.
3. The use of the selected alloys for making steel experimentally under a variety of conditions.
4. Physical and chemical tests of the steels so made to determine useful properties, and particularly the determination of the gas content of the steels before and after deoxidation.

ORGANIZATION AND PLAN OF THE RESEARCH

A committee composed of Henry M. Howe, R. B. Sosman of the Geophysical Laboratory and the author recommended to the National Research Council that it enlist the co-operation of certain research organizations. After some correspondence and many changes in personnel of the group, the melting points included herein were determined by the institutions noted below. After a suitable selection of co-operating laboratories had been made the results were obtained very promptly, but very serious delays were incurred on account of those laboratories which originally volunteered for the work failing, after several months' efforts, to produce results. These remarks are not made in any spirit of criticism of the laboratories which withdrew, but merely for the purpose of giving some information as to how a co-operative research of this character, involving several groups of workers, actually progressed.

After much consideration, it was decided to limit this work to oxides of the more commonly used deoxidizing elements—manganese, silicon, aluminum and titanium. On account of the large amount of labor which might otherwise be necessary, it was thought the work should be confined to binary and ternary systems. In order still further to limit the field these oxides were com-

bined according to an arbitrary plan, which, nevertheless, seems to represent the path along which possible new deoxidation practices might be developed. For this purpose it was assumed that the slags resulting from deoxidation would be of the following types: silicates, titanates and aluminates in the binary systems and silico-aluminates, aluminosilicates, aluminotitanates and titano-aluminates in the ternary systems.

The investigation of the system $Al_2O_3-SiO_2$ was omitted at the suggestion of Dr. Sosman, since work already done shows that combinations of these two oxides all melt above 1,500 deg. C. Experimental work on all mixtures of MnO and Al_2O_3 also showed them to melt above 1,500 deg. C.

While it would seem desirable to have ferrous oxide present in all the mixtures investigated, since it is always found in steel deoxidation slags, this was not done, because of the greater complexity which the investigation would then assume. It is believed, however, that the effects of such amounts of ferrous oxide as would probably be present in deoxidation slags would be in all cases to lower melting points, so that any desirable mixtures of low fusing point found by this investigation could be assumed to be still more desirable because of probable presence of ferrous oxide.

METHODS FOR DETERMINING THE MELTING POINTS

In general, it was thought that the choice of the method could be left to the laboratory doing the work, depending on its equipment in the way of furnaces, pyrometers, etc. It was, however, considered necessary that the melting point determinations should be made in a non-oxidizing atmosphere, since the deoxidizer in a steel bath usually does its work under such conditions. It was recommended by the committee that electrically heated furnaces be used, either of the vacuum type (Arsem) or furnaces which permit the circulation over the mixture of a non-oxidizing gas. Very convenient crucibles were devised for the work and were used by several of the laboratories. These were made of "Armco" iron, supplied by the American Rolling Mill Co., and were pressed out of this material in the thimble-manufacturing machines at the Scovill Mfg. Co.'s plant. The melting point of the "Armco" iron, on account of its freedom from impurities, approximates that of pure iron (1,530 deg. C.); it was thought that any slags melting higher than such crucibles would be of no value in the steel industry; consequently, if during an experiment the crucibles showed signs of fusion before the contents (oxide mixtures), the experiment was carried no further.

The mixtures were made at the Bureau of Standards from the following materials: As a source of manganese oxide, c.p. manganese carbonate was used, since this dissociates at the temperatures used to MnO and CO_2 . For the aluminum oxide c.p. calcined Al_2O_3 was used. For silica a good grade of quartz was ground to 200-mesh, digested for several hours with hydrochloric acid and then washed free of chlorides. For titanium oxide the best commercial grade of rutile concentrate carrying 97 per cent TiO_2 was used (3 per cent silica). In making the mixtures containing the TiO_2 , correction was made for the silica impurity.

These various substances were thoroughly dried and mixtures were then prepared by weighing the components and mingling them thoroughly by turning over several times on a sheet of paper with a large spatula;

after this they were passed through an 80-mesh sieve several times in order to insure a still more homogeneous mixture. Fifty-gram portions of each mixture were then placed in sealed manila envelopes and these were sent out by the National Research Council as directed. Many mixtures had to be returned to Washington and redistributed because of changes in the co-operators.

REFERENCE WORK AT BUREAU

As a check on the accuracy of the method used by each co-operating laboratory the melting point of one of the mixtures (No. 89, with 25 per cent Al_2O_3 , 20 per cent MnO and 55 per cent TiO_2 , melting point 1,370 deg. C.) was determined at the Bureau of Standards by R. G. Waltenberg, and portions of this were distributed to each co-operating laboratory, which reported its fusion point as determined by their method. The method used by the bureau for this determination was as follows:

The finely ground materials were moistened with water and molded into cylinders 1 cm. in diameter by 1.5 cm. long. These were air dried at least one day before use.

The melting points were determined by direct observation in an Arsem vacuum furnace.¹ The cylinders of oxide mixture were placed in "Armco" iron crucibles (these were scoured until free from internal surface oxide) and the latter placed in a magnesia holder supported on a graphite stand. The crucibles were placed slightly below the hottest part of the furnace so that any change in shape of the material was visible through the observation window of the Arsem furnace. The temperature was raised gradually until evidence of softening or melting appeared. Then the temperature was determined with an optical pyrometer. The melting point was taken as the temperature at which the material would flow. The gaseous pressure in the furnace was about 1 mm. mercury throughout the work. The mixtures contained manganese as carbonate from which carbon dioxide was liberated as the temperature was raised. Considerable shrinkage of the cylinders took place during this stage.

It was found that the temperature of initial softening was not much lower than the temperature at which the material would flow. This was verified by removing some of the samples from the furnace after heating just below and a little above the melting point. On one of the samples the melting point was determined on material which had previously been melted. This melting point did not differ materially from the first determination.

The method used by each co-operating laboratory is briefly described below.

General Electric Co., work in charge of W. E. Ruder: The method used was practically that employed at the Bureau of Standards in determining the melting point of the "standard mixture." Result, 1,370 to 1,380 deg. C.

Westinghouse Electric Co., work in charge of P. G. Nutting: The method used was that used at the Bureau of Standards. Result, 1,368 deg. C.

National Lamp Works of General Electric Co., work in charge of E. C. Bain: Cones of the materials shaped like standard pyrometric cones were heated electrically in a tungsten-wound furnace. Hydrogen was on the outside of the heated tube containing the cones and a

current of nitrogen was passed through the interior of the tube. The cones were supported on alundum boats. The temperature observations were taken with a Holborn-Kurlbaum optical pyrometer. Result, 1,400 deg. C.

¹See Scientific Paper 212.

The Norton Co., Niagara Falls, N. Y., work in charge of R. H. White: A horizontal, electrically-heated carbon tube furnace was used. Cones of the material 1 in. high were placed in the uniform-temperature part of the tube, two or more cones for each mixture, and the melting point checked by two observers. Nitrogen was introduced into the furnace by a fused quartz tube extending within 6 in. of the cones. Temperatures were observed with a Leeds & Northrup optical pyrometer. Result, 1,406 deg. C.

The FitzGerald Laboratories, Niagara Falls, N. Y., work in charge of F. A. J. FitzGerald: Cones of the materials were placed near standard Seger cones in a carbon tube imbedded in granular carbon heated by an electric current. The point determined was where the oxide mixture softened and bent over completely. Result, 1,380 deg. C.

Bureau of Mines, Pittsburgh, Pa., work in charge of A. C. Fieldner: Cones of the material were tested by the gas furnace method for determining fusibility of coal ash, as described in Bureau of Mines Bulletin 129, pp. 111-114. Result 1,388 deg. C.

Industrial Wastes in Relation to Water Supplies*

INDUSTRIAL pollution of water, like sewage pollution, is an unfortunate accompaniment of civilization. It is estimated that not less than 40 per cent of the population of the United States is supplied with water obtained from surface sources, and it is therefore evident that the preservation of the purity of the streams and lakes of the country is important. The effect of industrial wastes on public water supply is generally manifested in one or more of the following ways:

- (1) Disagreeable odors or tastes.
- (2) Foreign substances which make the water unsightly and unsuitable for use or else interfere with the proper functioning of the purification works.
- (3) Chemical substances in solution which, though not objectionable to the sight or taste, may cause actual damage to waterworks structure, render the water less fit for domestic or industrial use on account of hardness or other chemical properties and may or may not be detrimental to health.

Some of the instances of pollution having particular reference to the chemical industry are discussed. The more important are:

In recent years the increase of the byproduct coke works has added materially to the problems of water supply in those districts in which the works are located. The wastes vary in composition depending upon the process and the degree to which the products are worked up for the market. A complex group of substances referred to as "phenols" and its derivatives persist in the waste products from the works by reason of the relative solubility in water and give rise to the greatest offence to water supplies. Phenol will form substitution products with chlorine gas and calcium hypochlorite, in use generally for water sterilization, forming the intensely aromatic trichlorophenol.

The trouble arising from the wastes from wood distillation industries are more frequently those arising from the destructive distillation of hard woods, although

The accompanying tables give the results of the various determinations.

CONCLUSIONS

Seventy-three deoxidizing alloys, all of possible value to steel makers, have thus been shown to have melting points, when oxidized, somewhat below the melting point of pure iron—some of them considerably below. The relative or actual value of these can be determined by carrying out the other phases of the complete investigation mentioned in this paper.

The only basis this investigation furnishes for judging the relative merits of the deoxidizers is comparative fusing points of the slags. It may be expected that a deoxidizer which gives the deoxidation slag of lowest fusing point will be the best. Of the new oxidizers the most fusible are as follows:

Composition	Melting Point of Mixed Oxide Deg. C.
75 per cent Mn, 24 per cent Si.....	1228
41 per cent Mn, 59 per cent Ti.....	1160
49 per cent Mn, 18 per cent Ti, 33 per cent Si..	1130
13 per cent Al, 52 per cent Mn, 35 per cent Si..	1121
12 per cent Al, 47 per cent Mn, 41 per cent Ti..	1320

some trouble has been reported from plants using resinous wood. Spent still liquors and sludges, all of which have a penetrating odor and "smoky" taste peculiar to wood creosote, are the cause of most of the trouble. Unlike coal "phenols," the wood "phenols" are little affected by the chlorination process used in sterilization. No method has been found which is effective in removing objectionable tastes and odors caused by these substances.

The wastes from tanneries are objectionable from the fact that they cause additional expense in the proper purification of the water into which they are added as well as being unsightly.

The wastes from the paper and pulp industries have been the cause of litigation in those states where the waste from mills is run into streams.

It can hardly be denied that the prosperity of a nation is fairly measured by its industrial development. It is obvious therefore that the proper solution of the problem of industrial pollution does not lie in the forbidding of industry, but in a sane regulation whereby industries may flourish without detriment to the resources of the country. It is proper that the burden of preventing stream pollution should be placed on the industrial plants themselves. There has been too much carelessness by manufacturers in allowing obnoxious wastes to enter streams and too much disregard of the rights of the public, particularly in the use of streams. The manufacturers can often with little expense prevent the pollution of streams, and repeatedly it has been found that the unwilling adoption of a process for waste disposal has resulted in a clear profit to the manufacturer from the recovery of byproducts. On the other hand, it is apparent that the necessities of the public water supply have sometimes borne down rather heavily upon industries when remedies were at hand for offsetting the effects complained of. It must be admitted that water purification plants are very much stereotyped in design and fitted for handling the older problems of removing sewage effects. In this matter it would seem that "rule of reason" might often be put into effect, although it must be admitted that the structure of American law is not inclined much to the principle of "balance of conveniences."

Experiments in Manufacturing No. 12 Alloy

No. 12 Alloy May Be Conveniently and Economically Prepared by Charging Aluminum Ingot, No. 12 Ingot and Scrap and a Copper-Rich Alloy Into the Melting Furnace, and There Is No Advantage in Any Other Procedure

BY ROBERT J. ANDERSON*

FOR the purpose of securing comparative data with regard to the manufacture of light aluminum : copper alloys by the various methods in use, a number of experiments were carried out at the Gloekler Foundry Co., Pittsburgh, Pa. In these experiments No. 12 alloy heats were made up by the use of copper, 33: 67 alloy, 50: 50 alloy, and 60: 40 alloy.

METHOD OF EXPERIMENT AND MATERIALS

In all of the experimental heats, the endeavor was made to keep the conditions the same so far as possible, and the variables included time, temperature, and method of introducing the copper. The various heats were melted in plumbago crucibles in a gas-fired melting furnace, and sand castings were poured from each heat. Chemical compositions of the materials employed are given in Table I. No. 12 alloy scrap was used in some of the heats so as to approximate foundry practice more closely. Pouring temperatures were taken with a Wilson-Maeulen "pyod." Table II gives a summary of the experiments, and they are described in detail below. Chemical analyses of some of the sand castings poured in the various heats are given in Table III. The initial temperature of the hot crucible into which the materials were charged was taken as 600 deg. C., but this was somewhat variable—that is to say, between 400 and 700 deg. C.

USE OF SOLID COPPER

In the experiments carried out in the preparation of No. 12 alloy by alloying solid copper and liquid aluminum, the aluminum was melted in the crucible, and the copper added later. Two experiments in particular were carried out in order to observe the effect of agitation. In experiment G-1 the copper was added and allowed to sink to the bottom; no stirring was done, and the metal was poured into castings after standing for 30.0 minutes. In experiment G-2, the copper was added as in experiment G-1, but the melt was thoroughly stirred every few minutes. The melt was held in the furnace for 30.0 minutes, and was again well stirred before pouring into castings. The detailed data are given below.

Experiment G-1. In this experiment solid copper was added to liquid aluminum without stirring.

Charged aluminum into a hot crucible at 600 deg., lb.....	23.0
Time required to melt aluminum, min.....	23.0
Gas consumption, cu.ft.....	2,415
Temperature of the aluminum at the time copper was added, deg. C....	697
Charged copper, lb.....	2.0
Highest observed temperature of the resultant alloy, deg. C.....	765
Total gas consumption, cu.ft.....	2,940
Final temperature, deg. C.....	740
Pouring temperature of castings, deg. C.....	732
Weight of ingots and castings poured, lb.....	24.90
Weight of dross recovered, lb.....	0.20
Shrinkage, lb.....	+0.10
Loss due to oxidation and shrinkage, per cent.....	0.40

Experiment G-2. Here, solid copper was added to liquid aluminum with thorough stirring.

Charged aluminum into a hot crucible at 600 deg. C., lb.....	23.0
Time required to melt the aluminum, min.....	28.0
Gas consumption, cu.ft.....	2,940
Temperature of the aluminum at the time copper was added, deg. C....	685
Charged copper, lb.....	2.0
Highest observed temperature of the resultant alloy, deg. C.....	765
Total gas consumption, cu.ft.....	3,465
Final temperature, deg. C.....	750
Pouring temperature of castings, deg. C.....	744
Weight of castings and ingots poured, lb.....	24.70
Weight of dross recovered, lb.....	0.20
Shrinkage, lb.....	0.20
Loss due to oxidation and shrinkage, per cent.....	1.20

Some additional foundry experiments were made in the preparation of No. 12 alloy by adding copper directly. In one experiment, the copper was melted first and the aluminum added later; in the other, the aluminum was melted first and the copper added later, but the temperature of the aluminum in this experiment was considerably higher than was the temperature in experiments G-1 and G-2. These additional experiments are described below.

Experiment G-3. In this experiment, the copper was melted first and the aluminum added later.

Charged copper into a hot crucible at 600 deg. C., lb.....	2.0
Time required to melt the copper, min.....	23.0
Gas consumption, cu.ft.....	2,415
Temperature of the copper at the time the first aluminum addition was made, deg. C.....	1,128
Charged aluminum in small amounts every few minutes during 35 minutes, lb.....	23.0
Highest observed temperature, deg. C.....	1,195
Total gas consumption, cu.ft.....	4,515
Final temperature, deg. C.....	754
Pouring temperature of castings, deg. C.....	710
Weight of castings and ingots poured, lb.....	24.50
Weight of dross recovered, lb.....	0.50
Shrinkage, lb.....	0.00
Loss due to oxidation and shrinkage, per cent.....	2.00

TABLE I. CHEMICAL ANALYSES OF THE MATERIALS USED IN PREPARING No. 12 ALLOY

Material	Elements, per Cent—			
	Cu	Fe	Si	Al(a)
Aluminum.....	0.25	0.39	0.31	99.05
Light copper (b).....	99.89
Heavy copper (b).....	99.92
33: 67 alloy.....	33.05	0.50	0.36	66.09
50: 50 alloy.....	49.24	0.49	0.35	49.92
60: 40 alloy.....	59.29	0.53	0.32	39.86
No. 12 alloy.....	8.38	0.58	0.41	90.63

(a) Aluminum, by difference.

(b) The light copper was used in experiments G-1, G-2, G-4, and the heavy copper in experiment G-3.

Experiment G-4. Here, aluminum was melted first and the copper added later.

Charged aluminum into a hot crucible at 600 deg. C., lb.....	23.0
Time required to melt the aluminum, min.....	31.0
Gas consumption, cu.ft.....	3,255
Temperature of the aluminum at the time copper was added, deg. C....	715
Charged copper, lb.....	2.0
Highest observed temperature of the resultant alloy, deg. C.....	950
Total gas consumption, cu.ft.....	3,780
Final temperature, deg. C.....	928
Pouring temperature of castings, deg. C.....	720

USE OF 33: 67 COPPER: ALUMINUM ALLOY

Heats of No. 12 alloy were made up by using the 33: 67 alloy for introducing the copper. In foundry

practice, it is customary to charge the rich alloy and the aluminum ingot plus No. 12 scrap at once, and the whole charge is presumed to go down at once. As a matter of fact, the rich alloy, whether 33:67 or 50:50, melts first and the aluminum later. In making up No. 12 heats by the use of a rich alloy, it is possible to do this in at least three ways: (1) By charging the rich alloy and the aluminum together; (2) by melting the aluminum first and then adding solid rich alloy; and (3) by melting the rich alloy first and then adding the aluminum later. Also the aluminum and the rich alloy might be melted separately and the one poured into the other. Practically, the two methods used commercially are (1) and (2) above, but data with regard to (3) are also presented for the sake of comparison.

Experiment H-1. In this experiment, the required amounts of rich alloy, aluminum and No. 12 scrap were charged together.

Charged aluminum into a hot crucible at 600 deg. C., lb	9.47
Charged No. 12 scrap, lb	12.50
Charged 33:67 alloy, lb	3.03
Time required to melt the charge, min	23.0
Gas consumption, cu.ft	2.415
Highest observed temperature of the resultant alloy, deg. C	700
Total gas consumption, cu.ft	2.415
Final temperature, deg. C	685
Pouring temperature of castings, deg. C	672
Weight of castings and ingots poured, lb	24.70
Weight of dross recovered, lb	0.20
Shrinkage, lb	0.10
Loss due to oxidation and shrinkage, per cent	1.20

Experiment H-2. In this experiment, the aluminum plus No. 12 scrap was melted first, and the 33:67 alloy was then added to the liquid melt.

Charged aluminum into a hot crucible at 600 deg. C., lb	9.47
Charged No. 12 scrap, lb	12.50
Time required to melt this charge, min	25.0
Gas consumption, cu.ft	2.625
Temperature of the charge at the time the 33:67 alloy was added, deg. C	3.03
Charged 33:67 alloy, lb	1.0
Time required for the rich alloy to go into solution, approximately, min	710
Highest observed temperature of the resultant alloy, deg. C	3,150
Total gas consumption, cu.ft	710
Final temperature, deg. C	704
Pouring temperature of castings, deg. C	24.85
Weight of castings and ingots poured, lb	0.15
Weight of dross recovered, lb	0.00
Shrinkage, lb	0.60
Loss due to oxidation and shrinkage, per cent	

Experiment H-3. The rich alloy was melted first in this experiment, and the aluminum was charged later. No scrap was used.

Charged 33:67 alloy into a hot crucible at 600 deg. C., lb	6.06
Time required to melt the alloy, min	12.0
Gas consumption, cu.ft	1.260
Temperature of the alloy at the time the aluminum was added, deg. C	649
Charged aluminum, lb	18.94
Time required to melt the aluminum, min	20.0
Highest observed temperature of the resultant alloy, deg. C	720
Total gas consumption, cu.ft	3,360
Final temperature, deg. C	720
Pouring temperatures of castings, deg. C	710
Weight of castings and ingots poured, lb	24.60
Weight of dross recovered, lb	0.30
Shrinkage, lb	0.10
Loss due to oxidation and shrinkage, per cent	1.60

50:50 COPPER:ALUMINUM ALLOY

A number of No. 12 alloy heats were made up where the 50:50 copper:aluminum was employed for introducing the copper. The methods were practically the same as in experiments H-1 to H-3 where the 33:67 alloy was used.

Experiment I-1. In this experiment, the required amounts of aluminum, No. 12 scrap, and rich alloy were charged together.

Charged aluminum into a hot crucible at 600 deg. C., lb	10.5
Charged No. 12 scrap, lb	12.5
Charged 50:50 alloy, lb	2.0
Time required to melt the charge, min	30.0
Gas consumption, cu.ft	3,150
Highest observed temperature of the resultant alloy, deg. C	730
Total gas consumption, cu.ft	3,885
Final temperature, deg. C	730
Pouring temperature of castings, deg. C	711
Weight of castings and ingots poured, lb	24.75
Weight of dross recovered, lb	0.15
Shrinkage, lb	0.10
Loss due to oxidation and shrinkage, per cent	1.00

Experiment I-2. In this experiment, aluminum was melted first and 50:50 alloy was added to the liquid charge.

Charged aluminum into a hot crucible at 600 deg. C., lb	21.0
Time required to melt the aluminum, min	21.0
Gas consumption, cu.ft	2,205
Temperature of the aluminum at the time the 50:50 alloy was added, deg. C	690
Charged 50:50 alloy, lb	4.0
Time required (approximately) for the 50:50 alloy to go into solution, min	2.5
Highest observed temperature of the resultant alloy, deg. C	780
Total gas consumption, cu.ft	3,255
Final temperature, deg. C	780
Pouring temperature of castings, deg. C	710
Weight of castings and ingots poured, lb	24.80
Weight of dross recovered, lb	0.20
Shrinkage, lb	0.00
Loss due to oxidation and shrinkage, per cent	0.80

Experiment I-3. Here, the 50:50 alloy was melted first, and the aluminum ingot was added later.

Charged 50:50 alloy into a hot crucible at 600 deg. C., lb	4.0
Time required to melt the alloy, min	12.0
Gas consumption, cu.ft	1,260
Temperature of the alloy at the time the aluminum was added, deg. C	608
Charged aluminum, lb	21.0
Time required to melt the aluminum, min	18.0
Highest observed temperature of the resultant alloy, deg. C	715
Total gas consumption, cu.ft	3,675
Final temperature, deg. C	715
Pouring temperature of the castings, deg. C	706
Weight of castings and ingots poured, lb	24.60
Weight of dross recovered, lb	0.40
Shrinkage, lb	0.00
Loss due to oxidation and shrinkage, per cent	1.60

60:40 COPPER:ALUMINUM ALLOY

As has been mentioned previously, a 60:40 copper:aluminum alloy has not been used in the foundry, so far as is known, for introducing copper into aluminum. Since it is a brittle alloy and melts at approximately the same temperature as aluminum, it was thought to be worthy of trial. Accordingly, a number of heats were made up with this alloy.

Experiment J-1. The rich alloy, aluminum, and No. 12 scrap were melted together in this experiment.

Charged aluminum into a hot crucible at 600 deg. C., lb	10.84
Charged No. 12 scrap, lb	12.50
Charged 60:40 alloy, lb	1.66
Time required to melt this charge, min	30.0
Gas consumption, cu.ft	3,150
Highest observed temperature, deg. C	715
Total gas consumption, cu.ft	3,675
Final temperature, deg. C	715
Pouring temperature of castings, deg. C	711
Weight of castings and ingots poured, lb	24.80
Weight of dross recovered, lb	0.13
Shrinkage, lb	0.05
Loss due to oxidation and shrinkage, per cent	0.80

Experiment J-2. In this experiment, the aluminum and No. 12 alloy were melted first, and when liquid the proper addition of 60:40 alloy was made.

Charged aluminum into a hot crucible at 600 deg. C., lb	10.84
Charged No. 12 scrap, lb	12.50
Time required to melt this charge, min	24.0
Gas consumption, cu.ft	2,520
Temperature of this charge at the time the 60:40 addition was made, deg. C	645
Charged 60:40 alloy, lb	1.66
Highest observed temperature of the resultant alloy, deg. C	709
Total gas consumption, cu.ft	3,045
Final temperature, deg. C	709
Pouring temperature of the castings, deg. C	699
Weight of castings and ingots poured, lb	24.90
Weight of dross recovered, lb	0.20
Shrinkage, lb	+0.10
Loss due to oxidation and shrinkage, per cent	0.40

Experiment J-3. In this experiment, the 60:40 alloy was melted first, and the aluminum was added later. No scrap was used.

Charged 60:40 alloy into a hot crucible at 600 deg. C., lb	3.32
Time required to melt the alloy, min	10.0
Gas consumption, cu.ft	1,050
Temperature of the alloy at the time the aluminum was added, deg. C	700
Charged aluminum, lb	21.68
Time required to melt the aluminum, min	18.0
Highest observed temperature of the resultant alloy, deg. C	707
Total gas consumption, cu.ft	3,465
Final temperature, deg. C	707
Pouring temperature of the castings, deg. C	701
Weight of castings and ingots poured, lb	24.75
Weight of dross recovered, lb	0.25
Shrinkage, lb	0.00
Loss due to oxidation and shrinkage, per cent	1.00

Experiment J-4. Aluminum and 60:40 alloy were melted together in this experiment.

Charged aluminum into a hot crucible at 600 deg. C., lb.	21.68
Charged 60:40 alloy, lb.	3.32
Time required to melt the charge, min.	26.0
Gas consumption, cu.ft.	2,730
Highest observed temperature, deg. C.	730
Total gas consumption, cu.ft.	3,465
Final temperature, deg. C.	730
Pouring temperature of castings, deg. C.	710
Weight of castings and ingots poured, lb.	24.80
Weight of dross recovered, lb.	0.30
Shrinkage, lb.	+0.10
Loss due to oxidation and shrinkage, per cent.	0.80

DISCUSSION OF THE EXPERIMENTS

An inspection of the experimental details and the summary in Table II affords interesting data from which conclusions may be safely drawn. Both dross losses and gas consumption are high in the experiments where either copper or the rich alloys were melted first and the aluminum added later. Both dross losses and gas consumption are low when the entire charge is melted at once, or where the necessary rich alloy (or copper) is added to a liquid bath. There appears to be no advantage gained by adding solid rich alloy or solid copper to liquid aluminum as compared to charging all the materials together. In general, the higher dross losses result from higher temperatures, for example in experiments G-3 and G-4. In experiment G-3 the copper was melted first, and when at a temperature of 1,128 deg. C. aluminum was introduced. In experiment G-4, the temperature of the alloy, after the copper addition, was purposely raised to 950 deg. C., and the dross loss was consequently high. But few apparent anomalies appear in the summarized data, and it will be readily apparent that these may exist without vitiating the results because of the conditions of the experiments. As already explained, the initial charging temperature of the hot crucible was arbitrarily taken as 600 deg. C., but this varied considerably, as shown by temperature measurements. Consequently, gas consumption figures vary, but within reasonable limits. The difficulty of collecting all of the melt, after pouring castings and ingots, and

the practical impossibility of cleaning the crucible so as to recover all of the dross and the alloy sticking to the inside will lead to minor errors. Where there is a plus shrinkage, the materials were recovered most completely; the weight of the castings and ingots poured plus the dross should give a total weight greater than the weight of the original charge because of the oxidation of aluminum to Al_2O_3 .

In considering the dross and shrinkage losses in Table II, it should be borne in mind that the experiments were carried out on a small scale, 25-lb. charges being used. The relative order of the losses in preparing No. 12 alloy by the different methods is correct, but the actual figures are too high for large-scale practice. Moreover, it should be pointed out that ordinarily the dross is not

TABLE III. CHEMICAL ANALYSES OF SOME OF THE CASTINGS POURED IN THE NO. 12 ALLOY EXPERIMENTS

Experiment	Elements, per Cent

the castings poured, and these were examined for general characteristics. Practically no differences with regard to microstructure (distribution of the CuAl_2 , etc.) were found, but blowholes and porosity appeared to be more numerous and greater in the case of castings poured from melts which, at one time or another during preparation, had attained rather high temperatures. Furthermore, these defects were more pronounced in the castings poured from heats where the dross losses were high, viz., G-3, J-3, and I-3. Typical microstructures of sections cut from the castings are shown in Figs. 1 to 4, inclusive.

GRADE OF NO. 12 ALLOY HEATS

In papers which have preceded this,¹ it has been shown that the 92 : 8 aluminum : copper alloy is prepared by various methods, and there remains to be considered, in a brief way, the various grades of heats used in making this alloy. Ordinarily, pig aluminum alone is not used, but some No. 12 ingot, or foundry scrap, or both, is added to the charge. The proportions of aluminum and No. 12 ingot or scrap in heats for castings may, and do, vary from 0 to 100 per cent. Where both aluminum and No. 12 ingot or scrap are charged, sufficient rich alloy, say 50 : 50, is charged at the same time for the purpose of introducing the desired amount of copper. In foundry practice, it is economical, and usually necessary, to charge some No. 12 alloy with the aluminum; the No. 12 scrap charged will be made up of gates, risers, and defective castings from the foundry. Furthermore, if the castings are machined in a shop in conjunction with the foundry, large amounts of No. 12 borings will accumulate, and these must be disposed of. Also, some foundries buy back the borings from their castings in case the castings are sold to outside consumers. The petroleum involved in the economical han-

dling of borings is one which is solved in different ways. Some foundries send the borings to outside refiners or smelters; the refiner will run the borings into No. 12 ingot, and return the resultant ingot for a fee. This ingot is then charged into the melting pots with the aluminum and the rich alloy. Other foundries run down the borings into ingot themselves, while a few charge borings as such into the pots; the latter practice has largely disappeared. The handling of borings has already been dealt with by Gillett and James.²

In some places, no attempt is made to preserve uniformity in the matter of relative percentages in successive heats, while in other foundries this is guarded closely. One foundry, for example, uses the following charge: 25 per cent No. 12 scrap (gates, risers, defective and broken castings), 25 per cent No. 12 ingot (run down from borings), 50 per cent aluminum ingot (plus sufficient 50 : 50 rich alloy). This charge is used continually unless the scrap losses on the floor mount to unusually high figures, and it becomes necessary to work more of the defectives into the charges.

The kind and quality of the scrap and No. 12 ingot used in foundry charges should be carefully controlled, since much difficulty may arise otherwise. Under Bureau of Aircraft Production specifications for Liberty (and other) motor castings, no No. 12 scrap other than that originating in the manufacturer's plant was allowed in the make-up of charges. The influence of the quality of the melting charge upon the resultant castings is one which is important and interesting to foundrymen, but it cannot be dealt with in this paper.

SUMMARY

The conclusions arrived at from the experiments and foundry experience in the preparation of No. 12 alloy by various methods are these:

First, there is nothing which would lead to the belief that one rich alloy is any better than another, for introducing copper, from the standpoint of dross losses and gas consumption.

Second, small heats of No. 12 alloy may be made conveniently and cheaply by using light gage copper sheet or punchings; the solid copper should be added to the liquid aluminum, whereupon it will alloy at relatively low temperatures.

Third, where the production is large, as in a foundry pouring 25,000 to 50,000 lb. of castings in eight hours, it is safer to employ a rich alloy.

Fourth, the most convenient rich alloy available (taking into consideration brittleness, melting point, and ease of calculation) is the 50 : 50 alloy.

Fifth, the most desirable method of making up a heat is to charge all the materials together.

Those foundrymen who hold to the belief that the "most desirable" method of preparing No. 12 alloy is by adding light copper punchings or sheet to liquid aluminum base their arguments largely on the saving arising in not using a rich alloy. The objection has been made that with this method the resultant castings are likely to run "hard" and "soft." The objection is valid, but, as has been shown, this may be overcome provided the melts are thoroughly stirred. Segregation of the CuAl_2 is extremely likely when melts are made by this method unless stirring is performed thoroughly and often. "Hard" and "soft" castings are attributed to

¹"Foundry Methods for Light Aluminum: Copper Alloys," by Robert J. Anderson, *CHEM. & MET. ENG.*, vol. 23, No. 15, p. 735, Oct. 13, 1920.

²Gillett, H. W., and James, G. M., "Melting Aluminum Chips," *Bull. 108, Mineral Technology 14, Bureau of Mines, 1916.*

the fact that the first pour is lean in copper and the last relatively rich. This defect in the method is so serious that it renders the whole scheme undesirable in large foundries, particularly when the production is rushed. Danger of segregation will be greatly minimized if rich alloys are used for introducing the copper. Moreover, with unskilled labor at the melting pots, it is much safer to use a rich alloy. Further than that, there have been difficulties experienced, at times, by some foundries in obtaining a suitable and sufficient supply of copper. It appears that a small foundry can use the direct copper method to advantage, but a large foundry voluntarily puts fetters on itself when it adheres to this method solely. The No. 12 alloy may be conveniently and economically prepared by charging the aluminum ingot, No. 12 ingot and scrap, and rich alloy together into the melting furnace, and there is no advantage in any other procedure.

How to Paint Turpentine Tanks and Cars

Effective methods for painting the inside of turpentine tanks and tank cars have been described by specialists of the Bureau of Chemistry, United States Department of Agriculture, as follows:

When in contact with iron for any length of time, especially if the tank is only partly full, turpentine gradually turns yellow. This is due to the fact that on exposure to air, turpentine slowly absorbs oxygen and becomes slightly acid, causing corrosion of the iron, which goes into solution, causing the formation of the yellow or brown color.

Unless the iron is protected against the action of the acids formed when the tank has been emptied, and is full of air with a thin film of turpentine on the inner surface, tank cars in regular use for transporting turpentine soon become rusty inside. As ordinary paint, made from linseed oil and turpentine, will not resist the solvent action of turpentine, it is necessary to use a paint made from materials which are not affected by turpentine. One made according to the following formula, which makes about 8 gal., enough to give an 8,000-gal. tank two coats, is generally used for this purpose:

Methanol or denatured alcohol, gal.....	5
Orange shellac (pure), lb.....	24
Dry red lead, lb.....	24
Venice turpentine, oz.....	28

Dissolve the shellac in the alcohol. This operation, which takes some little time, is best done by putting the two in a can and allowing the mixture to stand, covered, for two or three days, stirring occasionally. After all the shellac has gone into solution, strain the liquid through cheese-cloth to remove any insoluble matter. Then warm the Venice turpentine until it flows freely and stir it into the shellac solution. This is now ready for use in making up the paint. When ready to use the paint, immediately before it is to be applied to the tank, from which all loose rust has been scraped or removed with a wire brush, mix the red lead with the liquid, being sure to stir thoroughly to break up all lumps. Apply with an ordinary paint brush to the thoroughly clean and dry surface. Brush the paint out well to prevent peeling. Allow the first coat to dry hard before applying the second coat.

When painting the inside of a tank with this preparation, or whenever it is necessary for a man to enter a tank which has held turpentine, some arrangement must be made to prevent inhalation of the alcohol or

turpentine fumes. A supply of fresh air can be pumped in to the workman through a pipe connected with either an air pump or a small blower like those connected with small portable forges. A gas mask with a container filled with broken pumice stone saturated with concentrated sulphuric acid, through which the air is drawn, may also be used. The absorption chamber must be recharged at least once a day. The pumice, in pieces about the size of a pea, should be steeped in the acid and the excess acid allowed to drain off before being placed in the container. Since concentrated sulphuric acid rapidly absorbs moisture from the air, thus losing its absorptive qualities, the acid supply and the pumice after saturation with the acid must not be exposed to the air any longer than absolutely necessary. A man should not remain in such a tank for more than four hours a day, and should come out sooner if he begins to feel unsteady, or if the muscles become "jerky." Continued work, day after day, in a tank with a methanol paint should be avoided, as the poisonous effects of methanol are cumulative.

Sugar Industry in Brazil

Every state in Brazil produces sugar cane. Reliable statistics, however, are not obtainable, as most of the production is for local consumption, reports Consul-General Haeberle of Rio Janiero. Moderate estimates give the approximate number of bags of sugar produced as follows in 1911, 1914 and 1917: 1911-12, 5,000,000 bags of 60 kilos (132 lb. each bag); 1914-15, 5,196,000 bags; 1917-18, 7,350,000 bags. The States of Pernambuco, Sao Paulo, Sergipe and Bahia lead in the production of sugar in the order named.

The cane is all crushed in the country. In many places in the interior rudimentary appliances, made of hardwood, are still used to crush the cane. These establishments, producing dark-brown cake sugar ("rapadura"), consumed by the laborers on the farm, do not figure in any statistics, and the total production cannot be estimated. It is large, however. Small American crushers with three vertical steel cylinders are often used on farms and in small factories, driven by human or animal power. Some factories have up-to-date machinery; only one factory so far, however, has introduced the diffusion process in Brazil—the Uzina Esther, in Sao Paulo, with a daily capacity of 125 tons of cane.

Most of the production is used for consumption in Brazil; only the surplus is exported. Exports in the years 1914 to 1919, inclusive, were in the following quantities (one metric ton = 2,204.6 lb.):

Kinds	1914 Metric Tons	1915 Metric Tons	1916 Metric Tons	1917 Metric Tons	1918 Metric Tons	1919 Metric Tons
White sugar.....	1,365	2,833	31,201	98,179	94,720	(a)
Demerara.....	20,876	22,064	12,974	10,541	8,984	(a)
Brown sugar ..	9,619	34,178	9,650	22,789	11,930	(a)
Total ..	31,860	59,075	53,825	131,509	115,634	69,429

(a) Classification not yet available.

Sugar cane in Brazil is not an annual plant; it remains on the fields for several years. Seasons of planting and crushing are governed by weather conditions, wet or dry, varying greatly according to the districts. As a rule sugar cane is planted during the rainy season and crushed when the dry season sets in. These seasons differ widely in the various parts of Brazil.

Legal Notes

BY WELLINGTON GUSTIN

Some Pitfalls of Selling

A broker's right to his commissions is involved in the action of Eugene Suter, a New York broker, against the Farmers' Fertilizer Co., recently decided in the Supreme Court of Ohio. The company had employed the broker to negotiate a contract for the sale of sulphuric acid to be manufactured by the company, the company agreeing with the broker to pay a brokerage of 1 per cent of the amount of the price provided for in such contract, to be paid as payments of the price were received by the company. Under this agreement the broker negotiated a contract between the company and the Aetna Explosives Co., whereupon it was agreed that the defendant company should proceed with the erection of a plant for the manufacture of sulphuric acid and sell and deliver to the Aetna company 600 tons of acid per month, commencing about April, 1916, and continuing thereafter monthly for a period of twelve months, deliveries to be made at defendant's plant, the Aetna company agreeing to pay for the acid on delivery at the rate of \$27 per ton of 2,000 lb., f.o.b. defendant's works, Columbus, Ohio. The contract expressly provided that a brokerage of 1 per cent on this sale should be paid by defendant company to the broker as payments were received. The defendant company erected its sulphuric acid plant and made various deliveries to the Aetna company between April and July, 1916, and paid brokerage thereon.

CLIENTS MAKE NEW AGREEMENT

However, in October, the defendant company entered into a contract with the Aetna company canceling the former contract and releasing the latter company from the obligations thereof in consideration of the payment by the Aetna company of \$45,000 and an agreement on the part of the Aetna company to repay any brokerage the defendant company might be compelled to pay beyond that admitted due on the \$45,000 cash settlement. Thereupon the broker was sent check for \$450, but this settlement was rejected by him, and this suit was brought to collect 1 per cent brokerage on the full amount of the original contract.

The defendant company contended that according to custom and usage among brokers in New York the plaintiff was entitled to commission or brokerage only upon the moneys received by the defendant under the original contract, and that the broker had been paid his full commissions on the moneys received under said contract.

INSOLVENCY OF BUYER SET UP AS DEFENSE

Further the defendant company claimed that shortly after it began shipping acid disputes arose with the Aetna company over the contract; that the latter failed to furnish cars for shipments as provided in the contract and refused to pay for the acid delivered; that the Aetna company became financially embarrassed, and in order to save itself and the broker from great loss on acid shipped and not paid for it entered into the cash settlement; that it made every effort to perform

the conditions of the contract on its part, but was prevented solely through the failure of the Aetna company and by its threatened and actual insolvency. Then the defendant company denied that it employed the broker to negotiate the contract with the Aetna company.

Upon hearing the evidence the jury was instructed to find a verdict for the defendant, Farmers' Fertilizer Co., and from a judgment against him Suter appealed. The Court of Appeals affirmed the trial court and a further appeal on error was made to the Ohio Supreme Court.

The first question decided was whether the broker had a valid contract of employment. The broker testified that he was employed by Young, general manager of the defendant. The president of the company denied that the general manager had any authority to make such a contract. But there were a number of telegraphic communications between the broker and defendant company on the subject, and thereafter the general manager entered into a written contract with the Aetna company for the sale of the acid. In this contract brokerage is expressly provided to be paid Suter. This contract was signed by the names of the two companies, and thereafter the company ratified this contract made by its general manager by entering upon its performance and by paying Suter certain commissions in accordance with its terms.

RIGHT TO COMMISSION RESTS ON CONTRACT

The Supreme Court said that the right of a broker to recover commissions rests upon contract, express or implied. The burden is upon him to prove that his services were rendered under employment by the principal, or that the latter accepted his agency and his acts under circumstances showing that he knew the services were being rendered on his account and while the agent was relying on the principal's obligation to pay him. If the services are rendered without employment, express or implied, or as a mere volunteer and without acceptance under the circumstances stated, he cannot recover.

Also, where a principal enters into a written contract of sale with a purchaser produced by a broker, in which instrument the principal agrees to pay the broker a specific compensation on "this sale," such action amounts to an acceptance of the services of the broker and ratification of his previous employment, even though such previous employment was made by an officer or agent who was without authority to make it.

On the question of the release of the Aetna company by defendant the rule was stated that where the obligations arising under a contract have attached, and subsequent thereto one party, without the consent of the other, does some act or makes some new arrangement which prevents the carrying out of the contract according to its terms, he cannot avail himself of this conduct to avoid his liability to the other party.

It appeared that the defendant company entered into the contract with the purchaser relying on its own investigations and knowledge of the ability of the Aetna company to carry out the contract, and because it was satisfied with the purchaser procured by the broker. Under such circumstances the release of the Aetna company from further performance of the contract on its part for the consideration named would entitle the broker to the immediate payment of his commission. Therefore the judgment of the two lower courts was reversed and judgment was ordered to be entered for the broker.

German Chemical Industries*

THE peace treaty requires that Germany shall deliver to France, during each of three successive years, 30,000 tons of sulphate of ammonia, 35,000 tons of benzene and 50,000 tons of coal tar. The Reparation Commission reserved the right to one-half the supply of dyestuffs and chemico-pharmaceutical products on hand at the time of the signing of the treaty; also an amount up to one-fourth of the product up to Jan. 1, 1915. Now that a year has elapsed since these provisions became effective, it is of interest to read the German reports of company meetings, chambers of commerce summaries, and trade-journal reviews of conditions in the chemical industry.

The two general conclusions that may be drawn from this published material seem at first to be entirely contradictory. The introductory pages of every report and summary discuss the shortage in coal and raw materials, the closing of plants, the scarcity and high cost of labor and the poor transportation facilities. As a consequence, a very great scarcity of the finished product is reported so that orders cannot be filled. Some reports specifically mention the French deliveries as the occasion of the shortage on the market. The impression of industrial hardship that is conveyed in these opening paragraphs is, however, offset at the end of the same reports by the financial statements that record, almost without exception, the declaring of dividends largely in excess of those of 1918. The explanation of the discrepancy is of course to be found in the heavy foreign demand at the high prices of the last few months of 1919.

Below are given a few summaries from the German *Annals of Economics and Statistics* (April, 1920), from the *Journal* of the Berlin Chamber of Commerce, from trade journals and from company reports.

RESUMPTION OF CHEMICAL TRADE DEPENDENT UPON COAL SUPPLY

Resumption of trade in chemicals is dependent upon the supply of coal. Shortage in coal has brought a large part of the industry to a standstill, or at least has caused great shortage in production. If, now, a shortage of raw material is to follow, such deficiency in the supply of sulphuric acid, caustic soda, pyrites, tar, sugar and casein will itself be traceable to the scarcity of coal. The *Rhenisch-Westfalia Zeitung* for March 1 says some relief was obtained at the end of February by the delivery of American coal which had been ordered but was not until then available.

The chemical industry seems to be at a standstill. The chemico-pharmaceutical industry is in some respects in a better situation than in January, in other respects in a worse position. Dyestuffs have shown a brief revival because of the receipt of a moderate amount of coal.

The shellac industry also makes an encouraging report. Soap reports run from "bad" to "fair." Asphalt and tar products suffered from lack of raw material. Coking plants, producing tar, ammonium sulphate and benzene, report a freight scarcity; business was in other respects improved over a year ago. Ethereal oils were sluggish, but improving. Benzene and turpentine were not coming on the market. Weak

conditions prevailed in the sulphuric acid and fertilizer industries; in the case of the latter, shortage of materials made it impossible to satisfy the demand.

The chemical industry suffered heavily during the past year by reason of the shortage of coal, which became extraordinarily acute toward the end of the year, causing many industries to close. The shortage in other raw materials became more and more serious at the same time that the world demand for chemical products became so insistent. At this juncture many foreign countries put an embargo on the importation of German products. Finally the 25 and 50 per cent deliveries required in the peace treaty affected the chemical market seriously.

REPORT OF BERLIN CHAMBER OF COMMERCE

The report of Berlin Chamber of Commerce for 1920 states that the chemical industry and the trade in chemicals, raw materials and auxiliary products suffered in war time greater changes than most branches of industry. Germany was in normal times heavily dependent upon foreign countries in many matters of production and distribution; this field was entirely cut off by the war. A transformation of the whole industry was the only solution. The brilliant achievements of those who had the matter in hand are testified to in the manufacture of explosives and artificial nitrates.

Increase in salaries and in wages of operatives as well as ever-rising costs of coal and raw material resulted, of course, in continuous increases in costs, which were accentuated by the shortage in coal and transportation. The effect was felt all along the line; the selling price was a mere barometer of conditions. No relief may be expected until the rate of exchange and inflated values have been brought back to normal. The demand is good, indeed almost impossible to meet, and yet production cannot possibly be accelerated.

GOVERNMENT CONTROL HEAVY DEMAND FOR MANY PRODUCTS

Government control of sulphuric acid and other basic products grew more rigid rather than more lax. The shortage of pyrites made it useless to attempt to meet the demand. The maximum prices were set higher and higher, but production was dependent upon more fundamental things than money.

Hydrochloric acid was released from control in March, 1919. After a few months' production conditions were such that sales could be made even in Scandinavia and Finland, so that business in this line may be said to have been good. There was also a heavy demand for Glauber's salts, a byproduct of hydrochloric; it was impossible to fill the demand in Scandinavia.

Liquid anhydrous ammonia was in great demand. The small production of ammonium carbonate never permitted market prices to be within reason. Raw material for ammonium sulphate was exceedingly scarce, and yet the maximum price was so low that manufacture was unprofitable. Nitrogen prices reached a business-profit level only toward the end of the year. The production of spirits of ammonia was obstructed at intervals, but it became profitable in time.

Potassium prices were raised again and again, but the demand was still so keen that production was worth while. Copper vitriol was in heavy demand, but speculation drove the prices to too high a point. There was also a strong market for citric acid, but the raw

*Prepared by the European Division, Bureau of Foreign and Domestic Commerce.

material could not be obtained in Italy. Wolfram, molybdenum and vanadium could be obtained only in very small quantities.

TRADE IN PAINTS AND DYES

The marketing of pigments and dyes was restricted in the early part of the year because of the revolution; later on conditions improved until it was even possible to export some to neutral countries. With the signing of peace, export to France, Belgium and Italy set in until pre-war figures were met, especially in Belgium and Italy. It is very agreeable to note that the French trade also promises to pick up. England is still holding off. America, once a favorite territory, is still closed to us, and it is doubtful whether after peace is ratified our export to that country can be built up again, since the dye industry is making such strides over there. Injuries as to the market in the Orient indicate that that trade is reviving. In general, it may be said that German pigments and dyes will hold their markets abroad.

The supply of coal, soda, sulphuric acid and chrome salts was so low that it was impossible to fill the orders that piled in at the end of the year. Then the 8-hr. day has become a vital obstacle, as it is impossible to put some of the manufactures on such a basis. Double shifts are no solution; overtime is prevented by the attitude of the workers' organizations, even though individuals are in favor of it. Except for these circumstances, we might be able to build up foreign credits as a means of procuring food.

PIGMENT AND DYE INDUSTRIES COMBINE

The pigment and dye industries have found it necessary to combine. The German "Bunt- und Mineralfarben Industrie" and the Union of German Dye Industries were formed. These organizations have justified their existence in arranging for allocation of raw materials and the establishing of fixed prices, putting an end to profiteering. Goods for foreign sale were put at a higher price, so as to equalize the low rate of exchange. Prices are now about the same for all consumers. Altogether, the dye industries are in a favorable situation, except for the shortage of coal and raw materials.

The lac and varnish industry had a heavier demand than in 1918, but could not meet this demand, as the 8-hr. day and scarcity of material prevailed almost throughout the year. In December the restrictions on copal, shellac, rosin and turpentine oil were removed; linseed oil is still under control.

Production is still behind the average of former years. Increased production could hardly be hoped for, in the face of the restriction on the importation of benzine. The industry suffered by reason of the allocation of the raw materials to organizations outside of the trade.

GLUE, ETC.—DRUGS AND HERBS

The bone-glue production has been about 50 per cent. Foreign glues rose to impossible figures.

Mineral oils and tar products are on a 30 to 40 per cent production basis. There was a ready sale at home. Export was forbidden.

The drug industry suffered excessively under a shortage of materials. Coal was scarce and operatives were in an unsettled state. In the fall a general strike threw the whole trade into disorder. The retail business had been bad enough during the war; last year conditions

were hopelessly bad. Small factories were forced to shut down. Even for medicine and science very little was obtainable. Outside interests got such control that profiteering was inevitable. The general public suffered as a consequence.

Medicinal herbs could not be obtained, as the women and children who formerly gathered them were employed in factories at higher pay. Herbs rotted in the fields and woods; prices rose to ten—even fifty—times their former level.

REPORTS OF GERMAN CHEMICAL COMPANIES

The Chemische Fabrik Griesheim-Elektron, of Frankfurt, declared in 1919 a dividend of 12 per cent, as contrasted with 7 per cent in 1918—and this after setting aside over 4,000,000 marks for depreciation. This company explains the profits as arising from increased value of pre-war stocks. The Chemische Fabriken of Urdingen explain similar profits through the sale of stock held abroad. The Aktien Gesellschaft für Anilinfabrikation ("Agfa"), of Berlin, reports gross profits of 24,877,000 marks in 1919, as compared with 13,700,000 marks in 1918, warranting a dividend of 18 per cent. The Badische Anilin und Sodafabrik closed its works at Ludwigshafen and Oppau in November because of shortage of coal; the nitrogen works at Merseburg shut down because of political disturbances. In all these cases only a fraction of full production was reached by June, 1919, and yet the firms report large profits by reason of the great rise in prices of dyestuffs. Over 60,000,000 marks were written off, and yet the firm declared net profits of nearly 30,000,000 marks, justifying a dividend of 18 per cent.

The Farbwerke, of Höchst-am-Main, report that manufacturing was largely at a standstill during 1919 and early in 1920, only the pharmaceutical departments producing normally. But here, too, export sales enabled the company to declare a 14 per cent dividend, as contrasted with 12 per cent in 1918, on a basis of net profits of nearly 25,000,000 marks, even after deduction of an extra expense of 80,000,000 marks in increased wages. The gross profits of the Chemische Fabrik Rhenania, of Aix-la-Chapelle, advanced from 1,938,000 marks in 1918 to 5,723,000 marks last year. The dividend was increased from 10 to 25 per cent. Kalle & Co., of Biebrich, reported that only a part of the more important departments were operating, and yet, after deductions for depreciation, the dividend was increased from 7 to 14 per cent. The report is pessimistic as to prospects for 1920.

PRICES OF FERTILIZER FOR SEVEN YEARS COMPARED

Some idea of this general rise in value may be gained from the following comparative table of fertilizer prices (kilo = 2.2046 lb.):

Fertilizers	1913	1914	1915	1916	1917	1918	1919
Thomaslag, phosphoric:							
Spring.....	3.84	3.92	4.56	3.28	5.76	6.33	8.96
Fall.....	4.00	4.08	4.80	5.76	5.76	6.33	18.72
Kainit, 12 per cent pure potassium:							
Spring.....	1.20	1.20	1.20	1.88	1.56	2.16	3.12
Fall.....	1.20	1.20	1.20	1.56	2.16	2.76	4.92
Potash, 40 per cent pure:							
Spring.....	6.20	6.20	6.20	6.80	8.20	16.40
Fall.....	6.20	6.20	8.20	10.20	14.00	26.80
Ground calcium carbonate	80	80	80	1.05	1.20	1.80	3.35
Lime	1.85	1.85	1.85	2.40	4.15	5.00	9.50

Synopsis of Recent Chemical & Metallurgical Literature

Developing France's Natural Water Power.—France's natural water power, known familiarly as the "houille blanche," continues to provide one of the most fascinating economic topics, now that the coal problem has become so difficult. About a year ago a committee, designated as the Commission des Forces Hydrauliques, was created officially, its duties being to investigate the water forces of France and establish a plan for the development of hydro-electric power plants. This committee recently rendered its report, which, as far as statistics go, is optimistic.

In round figures, the water power in France may be reckoned theoretically at about 9,000,000 hp. Of this amount, 1,165,000 hp. is in use. About 500,000 hp. additional is being equipped. Inside of fifteen years 3,000,000 more hp. should be realized. The rest remains available for eventual development. The 1,165,000 hp. now installed is capable of 850,000 kw. It furnished in 1919 effectively 700,000 hp. (570,000 kw.). The plants in course of construction will provide an additional 550,000 hp. (365,000 kw.).

The region of the southeast of France is the best developed thus far, with 750,000 hp. already installed, and with 290,000 hp. in course of installation. The southwest has 210,000 hp. and will have 75,000 more in a short time. The central section has 140,000 hp. and will have 125,000 more. The eastern district accounts for 25,000 and 10,000.

Existing plans, if realized, are to provide the 3,000,000 hp. additional of the program inside the fifteen years as projected. Of this total, 1,200,000 hp. will be in the southeast, 500,000 in the southwest, 400,000 in the center, 62,000 in the east. According to these figures, France then will stand in third place for water power among leading countries.

The United States is rated as having 30,000,000 hp., Canada 25,000,000, Norway 7,500,000, Sweden 6,750,000, Austria-Hungary 6,450,000, Italy and Spain about 5,500,000 each. Germany's water power is estimated at only 1,500,000 hp., and that of England at about 1,000,000 hp., but these two countries are richly compensated in coal.

Previous to the war the amount of capital invested in France's hydro-electric power plants was about 700,000,000 francs, of which 525,000,000 francs represented motive power and electricity, 100,000,000 francs for electrochemistry and electrometallurgy, and the remainder in traction enterprises. The preceding figures apply only to the important exploitations, and, as many smaller industries also are utilizing water power, it is safe to add at least 300,000,000 francs more to the total, so that about a billion francs is the figure for the global investment in the "houille blanche" in France at present. Or, if account is taken of the expenditures necessitated by the 500,000 hp. placed in operation during the war, the total investment is considerably more.

During this post-war period of high prices for material of all kinds, it is found that the cost prices for installations, which before the war varied between 500 and 800 francs per horsepower, have risen to a figure

between 1,000 and 1,600 francs. It is computed that, for putting into operation 3,000,000 hp., the expense must be calculated at three or four billion francs.

The official report suggests that, in the forming of concessionary companies, the government could participate as stockholder and thus be a party to profit or loss. The opinion is given that new companies should be exempted from taxes during the first five years.

The importance of the question of developing France's water power resources is shown in the simple equation: 8 millions of horsepower are equivalent to 40 million tons of coal.—*The Review*, Am. Chamber of Commerce, France, Sept. 1, 1920.

Influence of Manganese Content on the Life of Steel Ingot Molds.—Steel works and foundries commonly employ for casting of ingot molds an iron analyzing:

	Per Cent
Silicon	1.75 to 2.0
Manganese	0.4 to 0.6
Phosphorus, less than ..	0.15
Sulphur, less than ..	0.10
Carbon	3.5 to 4.0

Manganese was limited to 0.6 per cent in the belief that with a higher percentage the molds would crack after a very limited number of pourings.

Tests made by M. GROSCLAUDE (*Génie Civil*, Sept. 4, 1920, pp. 198, 199), covering a period of many years,

DIAGRAM SHOWING THE RELATION BETWEEN LIFE AND MANGANESE CONTENT IN INGOT MOLDS

have proved that an increase of manganese on the contrary lengthens the life of the molds. Thus, with ingot molds of the above composition the maximum number of pourings was 110, whereas as many as 250 were made with molds of the following composition:

	Per Cent
Silicon	1.5 to 1.8
Manganese	1.75 to 2.25
Phosphorus, less than ..	0.10
Sulphur, less than ..	0.05
Carbon	3.25 to 3.50

The average obtained with molds of this composition during two consecutive years was 175 pourings, with a minimum of 125.

The results of the tests are plotted in the accompanying figure, by which it is seen that the manganese content has a great influence on the life of the mold. No tests have been made with analyses between the points B and C.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Flameless Powder.—OSWALD SILBERRAD of Buckhurst Hill, England, has made a study of the conditions necessary for the production of propellant explosives which shall be flameless and smokeless when fired in guns of a specified size. An increase in the ratio of H-C-OH groups to NO₂ groups has been found to give the desired result. By the application of thermodynamics and internal ballistics it is possible to calculate the amount of carbohydrate material (preferably starch) which must be added to an ordinary propellant explosive in order to reduce the temperature of the gases emitted from the muzzle below the ignition point. The amount of starch to be added to 100 parts of propellant varies from 7 parts in the case of American pyrocollodion to 33 parts for Italian ballistite. Tables are given to facilitate calculations and proper methods of incorporating the starch are also discussed. (1,349,983; Aug. 17, 1920.)

Electrolytic Chlorate Cell.—The cathode of this cell consists of a shell or casing of metal such as cast iron. Interior partitions terminating below the rim of the casing divide the cell into several compartments. These partitions are connected with the casing so that they also serve as cathodes. A carbon anode is placed in each compartment and kept at a fixed short distance from the cathode by means of slate insulators. A porous asbestos cloth covers the cathode surface so that the hydrogen liberated is enabled to escape to the atmosphere without exerting any reducing influence on the electrolyte. An insulating plate of glass is placed in the bottom of each compartment to prevent short-circuiting due to the accumulation of conductive sediment. It is well known that in a cell of this type anode consumption is high when carbon is used as anode material. By making the compartments of different sizes, EDWARD A. ALLEN of Portland, Me., is able to use efficiently anodes which have been reduced in size by oxidation. Thus, the first compartment may be designed to take anodes 2 in. thick, the second 1½ in. and the third 1 in. Provision is also made for change in width of the anodes.* (1,351,886; Sept. 7, 1920.)

* **Electrolytic Detinning Process.**—The apparatus comprises a fixed vat for the electrolyte and a rotating hexagonal drum which is divided into longitudinal compartments by cathode plates projecting internally. The scrap which serves as anode material is placed in a removable permeable lining in each compartment. Insulators prevent contact between cathode and anode. (1,353,194, CECIL M. WALTER of Four Oaks, near Birmingham, England; Sept. 21, 1920.)

Ferrochromium.—Ferrochromium was formerly made to some extent in the iron blast furnace, but it was found that the limiting percentage of chromium which could be introduced into the alloy in the blast furnace was about 30 per cent. The most desirable commercial alloy contains about 60 per cent chromium. The

late JOSEPH E. JOHNSON, Jr., found that by enriching the blast with oxygen the temperature in the hearth could be raised sufficiently to produce alloys high in chromium and low in both carbon and silicon. A blast containing 40 to 50 per cent oxygen is suitable for this purpose. (1,354,491; Oct. 5, 1920.)

Magnesium Powder.—At the present time, the method used in manufacturing magnesium powder is to cast the magnesium into bars or ingots, which are reduced to powder by sawing, turning or milling. The cuttings produced are classified by screening, those too large for use being ground in some form of mill to reduce them to the proper size. This method requires a large and costly plant, and a very considerable outlay for labor to attend the large number of machines. The process is very slow and tedious, owing both to its nature and to the constant necessity of starting new cuts, replacing pieces of metal which are too short to be further treated, and re-casting the remnants into suitable shape. The large number of machines in motion and the difficulty of collecting the fine powder makes the plant an extremely dangerous one, as friction may at any time ignite the fine powder. Another of the disadvantages of this method is the difficulty of melting magnesium without considerable loss, so that the constant melting and re-melting of the metal to utilize the stubs of bars multiplies this loss. The product resulting from this method is far from satisfactory. Even after careful screening, the grains are not of uniform size, owing to their very irregular shape. When examined microscopically, the grains are found to be in the form of chips or shavings presenting knife edges which cause the grains to cling together, and also present a large amount of surface for oxidation. These characteristics of the powder render it unstable and difficult to deal with in certain applications. DAVID F. NICOL of Montreal, Canada, has found that powdered magnesium can be more conveniently prepared in the following manner: Magnesium is melted under a flux of lithium chloride in a closed vessel. The molten metal is discharged in a fine stream into a jet of nitrogen having sufficient velocity to break up the stream of metal into fine particles. The metal is chilled so rapidly by the cold nitrogen that practically no nitride is formed. (1,351,865; assigned to Shawinigan Electro-Metals Co.; Sept. 7, 1920.)

Bismuth Oxide.—Bismuth is a difficult metal to oxidize to produce lower oxides cheaply. By heating to fusion with an oxidizing agent such as sodium nitrate in the presence of chlorine, bismuth is rapidly converted into the yellow oxide Bi₂O₃. (1,354,806; ELTON R. DARLING of Montclair, N. J., assignor to Ellis-Foster Co.; Oct. 5, 1920.)

Aluminum Chloride.—In the manufacture of anhydrous aluminum chloride by the process of reducing bauxite or alumina in the presence of chlorine, it is necessary to supply heat to the mass to cause the reaction to proceed properly. Various expedients have been proposed but have not met with commercial success. FRANCIS C. FRARY of Oakmont, Pa., suggests the addition of aluminum to the mixture. The reaction between aluminum and chlorine is sufficiently exothermic to maintain the whole mass at the proper temperature. Aluminum dross containing about 40 per cent metallic aluminum forms an excellent raw material for this process. (1,354,818; assigned to Aluminum Co. of America; Oct. 5, 1920.)

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Rendering Non-Plastic Materials Plastic.—Small quantities of neutral or alkaline vegetable extracts are added with alkalis to clay or kaolin masses or non-plastic materials which are liquefied with difficulty by the addition of alkali alone. Neutral, water-soluble saponines or extracts of saponine-bearing plants such as seatwort, cookweed, sowbreads, ivy, chestnut-capsules are especially suitable. Alkaline cellulose-waste lyes and "cellular pitch" can also be used. (Br. Pat. 144,317—1919. A. WALTER, Frankfurt-on-Main, Germany, Aug. 5, 1920.)

Dyes From Natural Products.—Water-soluble dye preparations are obtained from animal or vegetable dye-yielding matters by extracting the raw material with organic solvents, evaporating the extract to a sirup or paste and fusing the product with a water-soluble metallic salt or solid organic acid. The same parent material may be extracted successively with more than one organic solvent, or first with organic solvent and then with water, to obtain different extracts for treatment. According to examples there are obtained a bluish-red dye for wool or silk by fusing an alcohol extract of cudbear with alum; a scarlet wool dye by fusing a pyridine extract of cochineal with cream of tartar; a reddish-mauve wool dye by fusing the same extract with alum; a blue wool dye by fusing an alcohol extract of turmeric with potassium ferricyanide; a navy-blue dye for wool or silk by fusing an alcohol extract of logwood with copper sulphate; a yellow or yellowish-red wool dye by fusing an alcohol extract of madder with alum; purple silk dyes by fusing an acetone or pyridine extract of madder with alum. Other specified materials are: As raw materials, Brazil wood or sanderswood; as solvent, amyl acetate; as fusion reagents, aluminum or ferric acetate, stannous chloride, potassium bichromate, or tartaric, citric, or oxalic acid. (Br. Pat. 144,336—1919. A. M. HART, London, Aug. 5, 1920.)

Removal of Cyanogen Compounds From Coal Gas.—Cyanogen compounds are removed from coal gas as calcium ferrocyanide by treating the gas in a lime purifier to remove sulphuretted hydrogen and carbonic acid, and then treating in the same purifier with slaked lime impregnated with a solution of salt of iron such as ferrous sulphate. The ferrous sulphate may be added to the lime in a tier of the lime purifier near the exit, and when the purifier is spent, the material from this tier is leached, or agitated with a dilute alkali to obtain alkali ferrocyanide. (Br. Pat. 144,398—1919. J. J. HOOD, London, Aug. 5, 1920.)

Separating Suspended Particles From Gases.—In the electrical separation of particles suspended in gases, the parasitic charges carried by freely moving nuclei, for instance nitrogen molecules, the formation of which lowers the efficiency of the precipitation process, are caused to deposit on sluggish particles in fine division and incorporated in the gases; these latter particles, which may be water, oil, etc., may be formed by condensation during the passage of the gas current, and may be either an addition to the gases or an original constituent. In the former case, the material may be added either in the liquid or vapor phases before the gases reach the dust-depositing chamber or in this chamber; and it may be introduced as a spray or may be taken up by the gases

in their passage through evaporating vessels or over moistened absorbent bodies. (Br. Pat. 144,701—1919. METALLBANK UND METALLURGISCHE GES., Frankfurt-on-Main, and J. E. LILIENFELD, Leipzig, Aug. 11, 1920.)

Welding Metal Sheets.—In a method of welding thin sheets or foils of aluminum or aluminum alloys—e.g., 0.005 to 0.100 mm. in thickness—to sheets of iron or of other metals having a melting point above that of aluminum, the surfaces of the foils and sheets are separately provided with an extremely fine roughening or matt before being placed together for welding. The consequent annealing of the iron which is necessary when ordinary aluminum sheets are welded to iron plates and then cold-rolled into sheets is thus avoided, and the melting or loosening of the aluminum prevented. The roughening may be produced by cold-rolling of the sheets and foils in separate packs. The iron sheets may also be roughened by brushes or by sand blasting, etching, etc. The sheets and foils are then separately annealed and are then placed together in an airtight manner with roughened surfaces inward. They are then heated to about 600 deg. C. and welded by passing through rolls, the pressure being such as to stretch the foil as much as possible, but to stretch the sheets only slightly. The composite sheets are then heated to 500 deg. C. to anneal the foil. (Br. Pat. 144,706—1919. METALLINDUSTRIE SCHIELE & BRUCHSALER, Baden, Germany, Aug. 11, 1920.)

Hydrogen.—In the iron-steam process of making hydrogen the waste gases of reduction which have been fully spent in passing through a retort or bench of retorts but which still contain reducing gases are treated for the removal of steam and some water vapor, carbon dioxide and sulphur dioxide and other sulphur compounds, and then passed to another retort or bench for effecting reduction of the charge therein; the waste gases may be passed into the furnace setting or discharged into the atmosphere. The process may be carried out with three sets of retorts or benches; while the first set is making hydrogen, the second set is receiving water-gas completely to reduce the charge therein, and the spent gases are treated as above described and passed to the third set; at the next stage, the second set is making hydrogen, the reduction of the charge of the third set is completed by water-gas, and the spent gases are after purification passed to the first set; and so on. To purify the spent gases, they are first passed through a scrubber packed with marble, coke, etc., and down which water trickles and removes the sulphur compounds, then passed through water or potash solution to remove carbon dioxide, and finally through a tubular condenser to remove steam and water vapor; or after passage through the first scrubber, the gases may be passed through a condenser, and afterward through a purifier charged with lime to remove sulphur dioxide. (Br. Pat. 144,751—1919. BRITISH OXYGEN Co., Westminster; S. W. BRAY, Ilford, and I. H. BALFOUR, Buckhurst Hill, Aug. 11, 1920.)

Decolorizing Glycerine.—In processes in which glycerine is recovered from solutions containing sulphuric acid by the addition of barium carbonate and oxalic acid, the glycerine is decolorized by adding the oxalic acid, preferably in the form of powder, before the addition of barium carbonate, and preferably in quantity above that necessary to precipitate the barium salts formed. (Br. Pat. 144,727—1919. ELEKTRO-OSMOSE AKT. GES., Berlin, Aug. 11, 1920.)

Current Events

in the Chemical and Metallurgical Industries

New York Section Meeting, A.C.S.

On Friday evening, Oct. 22, the New York Section of the American Chemical Society was addressed by President W. A. Noyes on "The Foundation for Chemical Development." Dr. Noyes compared the national censuses of chemists, which, at the opening of the war, gave Germany 30,000, the United States 16,000, England 5,000 and France 2,500. One hundred years ago, Liebig went to France to study chemistry under Professor Gay-Lussac. Upon his return to Germany he started the system of university research which led to the subsequent advance of his native land to the front in industrial chemical development.

Dr. Noyes traced the work of Hofmann, and its influence on synthetic dyestuff manufacture after the pioneer work of Perkins. He then took up the thread of American progress and cited the case of Dr. Willis R. Whitney, who taught at Boston Tech on Mondays, Wednesdays and Fridays, did research work for the General Electric Co. at Schenectady on the alternate days and spent his evenings on Pullmans. The efforts of Dr. Whitney have resulted in establishing a research organization ranking among the best in the world. To carry on such work, industries must have men of the highest technical and mental training and to supply these, the universities must have their co-operation.

In the absence of Dr. Harrison E. Howe, Dr. H. A. Bumstead, director of the Sloane Laboratory of Physics at Yale University and chairman of the National Research Council, spoke on the relation of the National Research Council to chemical development. He placed particular emphasis upon the revised tables of physical and chemical constants. From \$150,000 to \$200,000 will be required for the completion of these tables. Substantial amounts have already been pledged by a number of industries. The speaker closed with a reference to the opportunities afforded by the fellowships in physics and chemistry made possible through a fund established by the Rockefeller Foundation.

Meeting of Engineering Council in Chicago

The regular meeting of Engineering Council was held on Oct. 21 in Chicago, with J. Parke Channing in the chair. Resolutions were passed supporting several measures, chief of which were the model license law for engineers, the Nolan Patent Office bill (H.R. 11,984) proposing an increase in the personnel and salaries of the U. S. Patent Office, and the creation of a Department of Public Works.

M. O. Leighton, national service representative, opened the discussion on the bill for a national Department of Public Works by indicating the lack of interest on the part of the many societies and individuals in the promotion of this measure. While the Council was aware of the futility of any sustained support due to its own early termination, it authorized the promulgation of a letter to the societies calling for renewed enthusiasm. A bill of some kind will doubtless

be passed at the next session of Congress, but if the civilian engineers do not act quickly control will rest with the U. S. Corps of Army Engineers.

The model license law was adopted essentially in the form considered by the Council for the past year. It is in form for universal adoption by all states to permit bona fide engineers and architects to operate in any state without the present handicap due to the varying laws now in effect in several.

The names to be suggested to President Wilson as suitable candidates for members of the U. S. Shipping Board are those of Prof. H. E. Riggs, University of Michigan, Ann Arbor, and W. H. Adams, consulting engineer, Detroit, Mich.

The Council authorized support of a measure to secure adequate appropriations for the Federal Power Commission. Decision of the Controller of the Treasury has held the \$100,000 previously appropriated as unavailable. Money is needed especially for research work at the Bureau of Standards.

E. J. Prindle, chairman of the committee handling legislation increasing the number and pay of the Patent Office employees, reported the bill, H.R. 11,984, had passed the House at the last session, but was amended in the Senate committee by Mr. Smoot so as to reduce the force and pay. The Council passed one resolution calling on the Senate for a restoration of the bill to its original status and another calling on engineers for support similar to that originally rendered—i.e., by individual letters acquainting Representatives and Senators with the urgency for passing the measure without revision.

The next meeting of Engineering Council will be held in Washington, D. C., Dec. 16.

Marine Exposition, Chicago

The National Marine Show was held in the Coliseum, Chicago, Oct. 18 to 23. Among other exhibitors were the General Electric Co., the Crane Co., the American Steel Foundries Co., John A. Roebling Sons, Ferguson & Lange Foundry Co., the Valentine Varnish Co., the Lunkenheimer Co., the American Chain Co. and Fairbanks, Morse & Co.

While this exposition does not hold such direct interest as the Chemical Exposition for the men of the profession, nevertheless many manufacturers of chemical plants and from the chemically-controlled industries were interested from the point of view of problems involved in the export business. One of the notable features was a large relief map of the world showing all the trade routes and location of all steamship lines. The purpose of the exposition was to arouse interest in the constantly increasing importance of America's merchant sea power and the relation to its maintenance and national prosperity and the wealth and magnitude of lake and inland water shipping, to the end that this part of the nation's transportation may receive the serious consideration of all branches of industry.

Philadelphia Section Meeting, A.C.S.

The regular monthly meeting of the Philadelphia Section of the American Chemical Society was held Thursday evening, Oct. 21, at the Engineers' Club. The testimonial dinner in honor of Prof. W. A. Noyes, president of the American Chemical Society, was attended by forty members.

In his address, "The Foundation for Chemical Development," Professor Noyes reviewed scientific progress in chemistry in order to show that there is a tendency at the present time to get away from the old spirit of scientific research in the pursuit of more material things. He felt that through careful study and application of the principles underlying the classic researches, American chemists should stand supreme among the chemists of the world.

At the conclusion of Dr. Noyes' address, Dr. Pearson, chairman of the Section, called upon Dr. E. F. Smith, who for so many years was professor of chemistry and provost of the University of Pennsylvania, for discussion. Other speakers called upon were: Dr. H. F. Keller, of the Germantown High School; Prof. W. T. Taggart, newly appointed Blanchard professor of chemistry of the University of Pennsylvania; Dr. Abraham Henwood, of the Drexel Institute; Prof. O. L. Shinn, of the University of Pennsylvania; Prof. E. C. Bertolet, of the Philadelphia Textile School.

New Sugar Plant at Mt. Pleasant, Mich.

The Columbia Sugar Co. is building and expects to have in operation in a short time a 1,000-ton plant, designed by Harry A. Vallez, general superintendent of the company. Steel and concrete construction will be used in the main 255 x 70-ft. building as well as in the warehouses, limekiln, boiler plant and pulp house. The plant will be equipped throughout with electric power. Each unit is designed with an individual motor drive so that any unit can be out at any time without interfering with the operation of the others.

Two 1,000-kw. Allis-Chalmers turbines each capable of running the plant alone will be installed so that one may always be kept as a spare for emergency. Mr. Vallez will install two diffusion batteries of eight cells each of 212 cu.ft. capacity each. A rake type cossette conveyor instead of a belt will feed them. There will be two 11-ft. coil pans, one calandria, and quadruple effect evaporators. Twelve rotary filters, six of which will be used for the first carbonization, three for the second and three for the thick juice filtrate, are to be installed.

The pulp-drying house will be equipped with the Burman improved double-shell drier, with specially designed distributing plates so arranged that when the pulp first enters the drum it is broken up in such a way that none of it is burned. The result is a pulp of unusual whiteness. The furnaces of these driers are equipped with the new Jones Automatic Cleaning Stokers.

Beets will reach the factory in standard-gage railroad cars hauled by a motor-driven car pulley into a rotary car dumper capable of handling any size or type of car up to 60 ft. in length. The dumper clamps the cars, turns them over, empties and rights them in about three minutes.

From the dump the beets fall into a long hopper fitted with duplex feeders so arranged as to carry them to one central point to an inclined conveyor, which

in turn delivers them to the main belt over the storage bins. This belt passes through a tripper device mounted on a traveling bridge and so arranged that the beets are diverted into a reversible shuttle belt also mounted on the bridge. This belt will deliver them to any point on either side of the main belt up to the outer limit of the sheds, a spread of 125 feet.

Meeting of Sub-Committee on Standardization of Petroleum Specifications

An open meeting of the technical sub-committee on Standardization of Petroleum Specifications was held in the auditorium of the Interior Department building, Washington, D. C., Oct. 18, to discuss possible revisions in the Government specifications on gasoline, kerosene, fuel and lubricating oils. The meeting was called to order by Dr. G. W. Gray, chairman of the sub-committee, and the delegates were welcomed by Dr. F. G. Cottrell, Director of the Bureau of Mines, under whose auspices the meeting was held. Representatives of several of the Government departments and petroleum technical societies, a number of state oil inspectors and some of the leading oil refining and marketing companies and automobile manufacturers were present. The petroleum societies were represented by the American Petroleum Institute, National Petroleum Association, Western Oil Refiners Association and the Society of Automotive Engineers.

There proved to be very little criticism of the lubricant specifications, but the refiners were almost unanimous in asking that the 90 per cent point of the gasoline specification be raised a little. The use of the New Saybolt Fuel Oil Viscosimeter was advocated by the refiners, to test the fuel oils used by the Army, the Navy and the Shipping Board, to replace the specific gravity determination required at the present time.

On Oct. 19 the sub-committee met to consider these and other points in connection with the Federal specifications for petroleum products. All the present specifications were taken up at this meeting, including those for gasoline, kerosene, fuel and lubricating oils and greases, which have been published in Bulletins 1, 2, 3 and 4 of the committee, and the possibility of further specifications for other products was also considered. After two days' closed session the sub-committee adjourned on Oct. 20, with the announcement that a report would shortly be prepared for submission to the Presidential committee and that it was probable that this would take the form of a complete and revised code of specifications for all petroleum products which will supersede the four bulletins mentioned above.

Making Films of Industry

Due to the success which has followed the showing of the Bureau of Mines films portraying the development of the coal and oil industries, numerous applications have been received to make pictures of other industries. These films are made under a co-operative agreement by which the industry furnishes the funds and the Bureau of Mines supervises the making of the picture. "The Story of Asbestos" is just being completed. "The Story of Sulphur" is in process of production. Work soon will start on a film showing the best types of insulation and how it may be used to prevent loss of heat.

Improvements at the Factories of the American Window Glass Co.

Although hampered by shortage of labor and supplies, particularly coal, and lack of transportation facilities, the American Window Glass Co., in addition to its specialties, produced 2,636,101 50-ft. boxes of common window glass during the last fiscal year.

In spite of the difficulties encountered during the past this company, with an eye to the future, has made many changes and improvements at its various plants.

In its No. 1 factory at Arnold City, Pa., it was found necessary, in order to take care of its increased output, to build a second story cutting room. As the old batch plant was entirely inadequate, the company has let a contract for a new one which will handle the requirements of the plant with a fraction of the number of men now employed. Arrangements have been made to install conveyors in the No. 2 tank building, which has been shut down for repairs after an operation of three years and ten months. This installation will mean a saving of a large amount of labor in the daily operation of the machines and furnaces. Equipment for use of producer gas is also being installed.

A new tank is being built at the No. 2 factory at Jeanette, Pa., and conveyors for the cellar glass and back ladle skins are being installed. Extension to the cutting room and construction of a number of additional flattening ovens is under way.

Improvements at the No. 2 factory at Hartford City, Ind., consist of a new tank building and furnace which will be an exact duplicate of that at Factory 2.

In Monongahela factory No. 14, a producer plant and power house have been erected and installations of the producer gas flues to the flattening ovens have been made.

Fort Worth Acid Works Plant

The Fort Worth Acid Works, Fort Worth, Tex., is putting into operation a standard recovery plant for sludge acids. This plant is built along the lines of standard design used for a period of years by the Standard Oil Co., and Sinclair Refining and other large oil producers. The large number of successful independent refineries in the territory will supply ample sludge acids for this plant. These refineries have hitherto been experiencing great difficulty and considerable expense with respect to disposition of sludge and welcome the outlet this recovery plant affords.

The unique feature of design of the process consists in using the waste heat from the acid stills through the evaporating pans in place of the old-type direct-fired pans. This effects a large saving in fuel and eliminates one very heavy maintenance expense, since direct-fire pans are notably short-lived and expensive of upkeep. Both the raw and finished material are loaded into tank cars, compressed air being employed throughout the plant.

Failed to Appoint C.W.S. Officers

No authority has been given as yet for the appointment of Corps or Division Gas Warfare officers. A tentative table of the new Army organization does not include the Chemical Warfare Service. There is some speculation as to whether this indicates that the Chemical Warfare Service will have to continue its fight for recognition despite the fact that the Army reorganization act sets it up as a permanent part of the Army.

The Failure of Metals Under Internal or Prolonged Stress

The Faraday Society, Institution of Mechanical Engineers, the Institute of Metals, and probably also the Iron and Steel Institute contemplate holding, early in 1921, a joint general discussion on "The Failure of Metals Under Internal or Prolonged Stress," according to *Engineering* (London). While various aspects of the subject have already been discussed, some new matter will be placed at the disposal of the co-operating societies later in the year, and it is thought that this will afford an opportunity for a more comprehensive consideration of the subject than has yet been given to it. The problem to be discussed is the failure of metal articles as a result either of external stresses to which they have been exposed for any length of time, or of internal stresses arising from conditions of manufacture, such as cold work, unequal expansion or contraction during casting and subsequent operations, including rapid heating and cooling. It is intended that the subject of the discussion should include the phenomena known as "season cracking," "corrosion cracking," "fire cracking" and analogous forms of failure, and that iron and steel as well as non-ferrous metals should be dealt with. The scope of the discussion would permit of contributions relating to the properties and behavior of materials other than metals which might throw light on the phenomena covered by the title.

While invitations have been sent out to certain men to contribute, this by no means is intended to exclude participation on the part of anyone having new information on some aspect of this broad subject. Correspondence along these lines is therefore invited by the secretary of the joint committee, F. S. Spiers, 10, Essex St., London, W. C. 2.

Packing of Dyes, in Powder Form, for Dispatch to Foreign Countries

The following regulations have been issued by the United States Post Office Department regarding the packing of dyes, in powder form, for shipment to foreign countries:

Dyes, in powder form, must not be accepted for transmission in the parcel-post mails to those foreign countries admitting dyes in the parcel-post mails, except the dyes are packed in a tin or metal container and such container inclosed in a substantial outside cover, open to inspection, of fiber board or similar material, double-faced corrugated cardboard, or strapped wooden boxes made of material at least a half inch thick.

The inside tin or metal container must be one closed with a screw-top cover having sufficient screw threads to require at least one and one-half complete turns before the cover will come off, the cover of which must be provided with a washer, so as to prevent possible sifting of the contents.

This provision for the employment of screw-top tin or metal containers does not prevent the use of compression (friction) tin top or metal containers, if soldered in at least four places, or the use of lead-sealed tin or metal containers, provided the containers are labeled in printing so as to show the nature of the contents, the quantity, and the name of the manufacturer or dealer, and, in addition, the containers are inclosed in substantial outside covers, open to inspection, of fiber board or similar material, double-faced corrugated cardboard, or strapped wooden boxes made of material at least a half inch thick.

Acceptable packages of samples of dyes, in powder form, not exceeding 12 oz. in weight, and packed in accordance with the requirements of the Postal Union regulations, will likewise be received for transmission in the international parcel-post service, when postage is paid at the rate of 12c. a lb. or fraction thereof.

British Gray and Malleable Cast Iron Industries Form Research Association

A meeting was held in Birmingham, England, on Sept. 30 in connection with the proposal to form a British Research Association for the gray and malleable cast iron industries. Representatives of the industries concerned gathered from various parts of Great Britain. The chair was taken by M. Riddell, president of the Institution of British Foundrymen. Sir Frank Heath, K.C.B., of the Government Department for Scientific and Industrial Research, gave an address in which he outlined the terms upon which the government would assist the scheme. The main features of the plan are that firms in the industry which join the association shall each guarantee a minimum annual subscription for five years: then, with a definite minimum income guaranteed, the government will assist the association with grants of money pound for pound, but at the end of the 5-yr. period will gradually diminish its contribution as the scheme becomes self-supporting. The government will require certain conditions to be fulfilled, and urged, without making it an absolute condition, that labor should be represented on the council of the association.

Sir Frank described each firm's subscription to the scheme as an insurance premium against the evil effects of ignorance. Dr. Leslie Aitchison (Birmingham) moved and F. J. Cook (Birmingham) seconded a resolution to the effect that "A Research Association for Gray and Malleable Cast Iron be formed." W. R. Barclay (Birmingham) and B. Collitt (Lincoln) spoke in support of the resolution, which was passed unanimously. A provisional council was then elected to proceed with the formation of the association.

During the meeting several of the speakers referred to the success of the researches carried out on behalf of the American Malleable Castings Association, and one of them made a strong plea for the abandonment of the present system of grading pig iron by fracture, and for the adoption of grading by analysis.

Canada Amends Denatured-Alcohol Regulations

A change in the regulations governing the denaturing of alcohol for industrial purposes has been made by the Canadian Government, with a view of making industrial alcohol available to the arts and industries at a more reasonable price than at present. Circulars are being sent out by the Canadian Department of Inland Revenue authorizing the manufacture and sale without restriction of a new grade to be known as Grade 2 benzol. The denaturants used in this are benzol, nitrobenzol, and pine oil, and the cost of these denaturants will be very small as compared with the cost of methanol, which was formerly the only denaturant allowed to be used. The cost of the denaturant, it is stated, is responsible for the high cost of industrial alcohol, and therefore a committee of three members of the Department of Inland Revenue, with two from the research council, held several meetings to decide on the form of a new and cheaper denaturant to be allowed.

While nine distilleries have been licensed for the manufacture of industrial alcohol, it is stated that only two have yet begun the work. The operation of prohibition in Canada had reduced the output of the distilleries to a great extent, and some of these had closed down entirely. As a result, there is a great shortage of alcohol for industrial purposes.

Glasgow to Make Chemicals From Gas Residuals

The Chemical Works Department of Glasgow Corporation, which was instituted about eighteen months ago as an adjunct of its gas department for the purpose of manufacturing chemicals from the gas residuals, will, it is expected, help to reduce the cost of gas to consumers, reports Consul G. E. Chamberlin of Glasgow, Scotland. It was the custom until about a year ago for the corporation to dispose of the residuals to private firms, from which it received a sum for the use of the buildings and equipment and a certain amount for the materials. When the chemical department was formed experiments were carried out which resulted so favorably that the municipality decided to terminate the contracts with the private firms and to undertake the whole of the work itself.

It is proposed to center the refining processes at the Provan works and to carry on crude distillation at the three other gas works and to increase the existing plant considerably. Refining will commence at once. The principal chemicals to be manufactured are motor benzene, pure benzene, toluene, solvent and heavy naphthas, and carbolic acid. The department will also consider the advisability of making dyes and intermediates. From the new installation about 100 tons more of tar will be made per day. The revenue last year from tar and ammoniacal liquor was \$1,491,950, and a conservative estimate places the net revenue from these sources for the current year at \$1,946,600.

Believes Gas Warfare Will Be Developed

Efforts to rule out the use of military gases by treaty are not likely to be successful, in the opinion of General A. A. Fries. Gas warfare gives a very great advantage to the intellectual and more highly developed peoples, General Fries points out. As a nation develops intellectually there is a tendency to lose in brawn. The development of chemical warfare has put in the hands of the more highly developed nations, General Fries says, a weapon which would render them absolutely safe from successful attack from any invader who might happen to have more brawn. Gases, he says, form the ideal weapon of the highly civilized man. "When gunpowder was introduced in warfare, says General Fries, similar protests were made against its use.

General Fries also points out that since the gases used in chemical warfare are also widely used in industries, there could be no agreement to stop their manufacture.

Looking for Chief Chemist for Edgewood Arsenal

Despite intensive efforts on the part of General A. A. Fries, head of the Chemical Warfare Service, to secure a chief chemist to direct the chemical research work at Edgewood Arsenal, his quest has been unsuccessful. Men with the requisite experience receive better salaries and have other advantages which the Government cannot offer. General Fries is hopeful, however, of finding someone who is in a position to make the necessary sacrifice to take the position.

Nitrate of Soda Movement

Of the 148,338 tons of nitrate of soda which moved through the Panama Canal during August all but 46,000 tons was destined to American ports. The remainder went to the European ports.

A Home for the National Academy of Sciences and the National Research Council

A site for the new building in Washington which is to serve as a home for the National Academy of Sciences and the National Research Council has recently been obtained. It comprises the entire block bounded by B and C Sts. and Twenty-first and Twenty-second Sts., N. W., and faces the Lincoln Memorial in Potomac Park. The Academy and Council have been enabled to obtain this site, costing about \$200,000, through the generosity of friends and supporters. Funds for the erection of the building have been provided by the Carnegie Corporation of New York.

Bureau of Mines Succession

Since there is such difference of opinion as to which industry should be represented by the chief of the Bureau of Mines, the suggestion is now made that Dr. F. G. Cottrell, the incumbent, may withhold his proposed resignation and continue in the position of director.

Personal

J. J. ARNFIELD, advertising manager of Fairbanks, Morse & Co., was elected president of the Engineering Advertisers' Association of Chicago, to fill the vacancy made by the resignation of A. H. Hopkins.

Dr. W. D. BANCROFT, professor of physical chemistry, Cornell University, Ithaca, N. Y., has been engaged by the Norton Co., Worcester, Mass., in a consulting capacity, in connection with its research laboratories.

HOWARD E. BATSFORD is now associated with the newly incorporated American Electric Graphite Mfg. Co., Toronto, Ohio, in the capacity of technical director.

GEORGE GRANGER BROWN is now a member of the staff of the department of chemical engineering, University of Michigan. He was formerly production manager of the Union Special Machine Co.

GEORGE F. DOWNS, president of the Lackawanna Steel Co., Buffalo, N. Y., has been elected a director of the American Iron and Steel Institute, to fill the vacancy caused by the death of Charles H. McCullough, Jr.

ANDREW M. FAIRLIE, sulphuric acid engineer of Atlanta, Ga., has been retained by the Baugh Chemical Co. as consultant in connection with the maintenance and economical operation of its sulphuric acid plants at Baltimore.

WILLIAM A. HAMOR, of the Mellon Institute of Industrial Research of the University of Pittsburgh, has been appointed a member of the National Research Council in the Division of Research Extension.

PAUL E. HOOD has recently taken charge of the experimental department of the Chicago factory of the Marden, Orth & Hastings Corporation.

C. O. JOHNS, who has been for a number of years chief of the color laboratory of the Bureau of Chemistry, has resigned to become director of research of the Standard Oil Co. of New Jersey. Dr. Johns will take up work at his new position about Nov. 15. His work on fundamental problems of the oil industry will probably be conducted at the main plant of the company, near Newark.

R. G. RICH, of the Quigley Furnace Specialties Co., has been appointed assistant manager of the Pittsburgh office, Oliver Bldg.

THEODORE J. SCHAUB has resigned his position as assistant general sales agent of the Crucible Steel Co. of America, to take the position of general sales manager of the Union Electric Steel Co., Carnegie, Pa.

Dr. CHARLES P. STEINMETZ addressed the joint meeting of the American Institute of Electrical Engineers, the Western Society of Engineers and the Chicago Chemists' Club in Chicago, Oct. 20, on the subject "Origin and Energy of the Lightning Flash."

LELAND R. VAN WERT is now with the Harvard Engineering School, Cambridge, Mass., as instructor during the first semester. Two courses in non-ferrous metallurgy will be given.

HILLER ZOBEL has come East from Death Valley, Cal., to engage in industrial chemical engineering research for the Pacific Coast Borax Co., Bayonne, N. J.

Current Market Reports

The Iron and Steel Market

Pittsburgh, Oct. 29, 1920.

The remaking of the iron and steel market is now in full progress. The developments, while apparently mixed in character, are those naturally indicated by the conditions that have preceded. The usual and familiar course of the iron and steel market is being followed except as the peculiar circumstances of the past ten months or thereabout make departures from the normal course natural and necessary.

The chief divergence of the market from a normal course was that prices of the independent steel producers rose far above those maintained by the United States Steel Corporation, and by different amounts at that. Thus there were not simply two markets, there was an indefinite number of markets. If there had been a uniform rise on the part of all producers the liquidation would be uniform. Instead, we have it that nearly all the independent steel producers have curtailed production, while the Steel Corporation's operations continue at the maximum permitted by physical conditions. More than that, there is curtailment common to independents whose position varies. Some, that pursued relatively moderate policies in making prices, have large quantities of business on books, but on account of cancellations and suspensions and postponements of deliveries are unable to predicate a full operation on their order books. These independents are not cutting their prices for the purpose of securing additional business, for to do so would be to jeopardize the contract business they already have. Other independents, with lean order books because they were doing chiefly a prompt business at the particularly high prices prompt deliveries made possible, are cutting their prices, but still do not secure enough orders to operate full, and they curtail production also, though quite differently positioned from the independents first mentioned.

Production of steel at this time is probably about 10 per cent below the rate in August and September, with the curtailment wholly on the part of independents. The Steel Corporation is operating at about 89 per cent of its rated capacity, but its capacity ratings are conservatively low.

EQUALIZATION OF STEEL MARKET PREDICTED BY APRIL

Whether the open market on steel products or that made by the independents will fall rapidly or slowly may depend upon how many independents seek business where it may be found and how many hold aloof, rather depending for operation on their contracts. As to the extent of the decline, the prediction commonly encountered is evasive, since it is that the independent market will decline to the Steel Corporation level, and as to what that level will be in future there is complete uncertainty. Some predict that the corporation will slightly advance its prices, more or less by a horizontal movement, others predict that there will be no material change, while still others predict that the corporation will make a number of reductions, not horizontal, but by way of equalization according to manufacturing costs, the alignment of which, between the various steel com-

modities, has materially altered in the past year and a half. A common prediction is that the market will be equalized, and on a sound basis, by next April, with a buying movement to occur then or by June at the latest.

WEEK'S DEVELOPMENTS

The independent producer which began last week to quote merchant bars at 2.35c., the Steel Corporation price, has withdrawn the quotation, and the bar market appears steady at 3c. to 3.25c., with scarcely any new business being booked.

The softening in strip steel has continued, with 5c. for hot rolled and 8c. for cold rolled the common quotation. Special prices on cold finished steel bars have disappeared, the market being fairly steady at 4.10c.

Sheets have continued to soften, 6.50c. being now a common quotation on black even for prompt shipment, while 8.75c. is exceptional and 9c. common on galvanized, blue annealed being generally on the basis of 5c.

PIG IRON AND COKE

The collapse in pig iron and coke has been phenomenal. Following the general advance in pig iron in August, marked more by the price advances than by the tonnage volume of the buying, there came first a period of no demand, and since then there has come a sharp diminution in demand against contracts. Many consumers have instructed merchant furnaces to decrease the rate of shipping against contract, while some have ordered complete suspension. According to trade practice pig iron contracts are not susceptible of cancellation, as is frequently the case with contracts for finished steel products, but the rate of delivery is much at the option of the consumer.

Following the disappearance of buying of pig iron, prices have shown a tendency to decline on each appearance of an inquiry, while with shipping requirements greatly reduced many furnaces have decided to bank or blow out, and the suspension of shipments of Connellsville coke on the customary "requirement contract" has thrown enough coke on the open market to cause spot prices for furnace coke to toboggan. At this writing the market has declined from \$17 to \$10 in nine business days.

On limited transactions in basic pig iron, chiefly a sale of 1,500 tons by a valley furnace interest to a Pittsburgh district consumer, the quotable market on basic iron has declined from \$42 to \$40 valley furnaces. On an inquiry for 200 tons of foundry iron for Pittsburgh delivery several valley furnaces showed great willingness to quote \$45 furnace, but the business went to another district, at a delivered price still lower than the equivalent of \$45 valley, which would be \$46.96 delivered Pittsburgh. Bessemer pig iron experienced a \$2 decline, to \$45 valley, in still more ignominious manner, since bessemer iron has been offered at \$45 valley without finding any takers at all.

Pig iron and coke are declining, but it cannot be said that they are seeking their level, since in present circumstances no price can be adjudged a proper one. Coke cannot find a legitimate level when there is such an absence of demand, and pig iron cannot find a proper level when the prospective cost of coke is in doubt.

The Chemical and Allied Industrial Markets

New York, Oct. 31, 1920.

One of the most important features of the chemical market is the large amount of supplies accumulating in the hands of dealers who are finding it difficult to convince buyers that the present prices are fair to both parties. The competition brought about by this condition is weakening the market and inquiries for spot material are subject to source and amount desired. On the other hand, there have been no important changes by producers who maintained their prices at recent levels. *Aqua ammonia*, 26 deg., is now available at 9½c. per lb.; the prevailing dullness has affected this item, which until a short time ago was very scarce, and as a result it has fallen off from the former low price of 10½c. per lb. The weakness in *copper sulphate*, crystals, continues with concessions being offered as low as \$7.50 per cwt. in car lots and ranging upward to \$9 in less

car lots. *Sodium cyanide* is one of the few items that has remained firm throughout the present weakness, as the demand for this material has not been influenced to any extent. Producers' prices have remained steady and current quotations of 26@30c. for car lots and 32@35c. per lb. for less car lots still prevail. There is a noticeable weakening in *sodium bisulphate* and the supplies on hand are ample to meet the very low demand; \$7@7.50 per ton is the latest quotation for car lots.

Movement among the *acids* has been downward, as the table below indicates. Buying is exceptionally weak with consequent surplus of supplies.

	DROP IN ACIDS			
	To-day	Last Week	Last Month	Last Year
Chloric	60 ½ 65c.	70 ½ 75c.	78 ½ 80c.	85c. @ \$1.00
Oxalic	32 ½ 31c.	35 ½ 36c.	45 ½ 50c.	22 ½ 24c.
Phosphoric	19 ½ 20c.	20 ½ 23c.	22 ½ 23c.	10 ½ 11c.
Tartaric	60 ½ 65c.	70 ½ 73c.	75 ½ 80c.	\$1.20-1.40

COAL-TAR PRODUCTS

The downward movement in this market has been confined to the intermediates, and even among these it has been slight, as the market is stagnant, with buying at a minimum. In order to attract business concessions are being made on many items. Among these are *aniline oil* and *salts*, the former being listed at 27@30c. and the latter at 33@34c. per lb. *Benzidine base* is also weaker, with current quotations ranging between \$1.25@1.30, which represents a 10c. drop compared with the recent price of \$1.35@1.40 per lb. The *crudes* still maintain the firmness that has been characteristic, although *phenol*, in good supply, is a little easier at a low figure of 11c. per lb.

WAXES

Although buying, as in every other line, has fallen off considerably, the waxes have remained comparatively steady. *Japan* is firm at 18@21c. per lb. and *montan* is a trifle easier at 12@14c. The large supply of *beeswax* on hand has weakened this item considerably and refined dark can be had for 30@32c., while the light is down to 33@36c. per lb.

The Chicago Market

Chicago, Oct. 27, 1920.

Buyers refuse to be tempted even by prices which would have seemed ridiculously low a few months ago. Their offers in most lines are kept at just a little below sellers' asking price, most sales apparently being consummated at a reduction from nominal quotation. By the simple process of buying in meager quantities and that only when the price is satisfactory, the market is being gradually forced down.

In the oil market the combination of cheaper live stock and consequent lower animal oil prices, apparently unlimited crops of flaxseed, corn and peanuts, and the serious curtailment of the textile industry has failed to shake the confidence of some holders of heavy stocks, although current quotations are apparently lower than costs. This feeling of anticipation of a stronger market seems to be based on the belief that stocks in the hands of consumers are unusually low and that a slight increase in industrial activity will promptly act to elevate the entire list.

HEAVY CHEMICALS

Material reduction in the price of *methyl alcohol* has failed to stimulate buying to any great extent and 97 per cent is now quoted at \$2.87 per gal. *Ethyl* grade is practically unchanged at \$5.60@5.70 for 190 proof. Old quotations are being maintained nominally on *denatured*, although current transactions are going for about 10c. less, sales being recorded as low as 96c. per gal. Lowered demand and better supply have operated to further weaken *bleaching powder*, a definite price being difficult to name, 6½c. per lb. being probably a fair quotation. *Sal soda* is a little heavy, though the price is unchanged at \$2 per cwt. in reasonable quantities.

Buyer and seller seem deadlocked on *glycerine*, stock being held at about 25c. for dynamite grade, with buyers' offers a cent lower. Actual transactions were negligible

during the period. *Alum* is firm, the market being in producers' hands. *Ammonia lump* is held at 51@54c. per lb. and *potash lump*, though less in demand, is equally firm at 84@87c. *Antimony* is in free supply and is quoted at the low figure of 9c. per lb. for the powdered needle grade. Acid prices are all weak and supply seems more than adequate for all demands.

COAL-TAR PRODUCTS

Curtailement of operations by textile mills and tanners has accentuated previous weakness. *Aniline oil* and *aniline salt* are both off another cent, now being obtainable at 26c. and 33c. per lb. respectively. *Naphthalene* is changing hands in small quantities only and at prices as low as 104c. per lb. for flakes. *Phosgene* is back to normal, 50c. per lb. ruling on a quiet market.

VEGETABLE OILS

This market is also dormant. Producers of *corn oil*, not caring to come into the market at the prevailing price of 93c. per lb. f.o.b. works, are further curtailing operations. Visible stocks are low, but consumers show no anxiety for goods. *Linseed oil* continues to drop, jobbers' barrel price now being \$1.20 per gal. November delivery is offered at 95c. in tanks and 5c. less is freely talked. *Red oil*, nominally 10c. per lb., shows no activity. Bear talk has forced *soya bean oil* down another half cent to 82c. in sellers' tanks f.o.b. coast and 174c. for local spots. At these prices buyers display small interest.

The St. Louis Market

St. Louis, Mo., Oct. 25, 1920.

After the slight changes reported in the last St. Louis market report the chemical market here seems to have become more stable and practically no changes are to be noted in the last two weeks. While everything is and probably will be quiet for some time, the general tone of the market is healthy.

Buyers here, as well as in other markets, are marking time to some extent, but this fact has not caused any cut in production nor is it likely that it will result in price reductions on a general scale. As a matter of fact the last market report noted several small advances, and these prices are continuing firm. Producers here feel that heavy chemical prices are not too high in consideration of the cost factor and a steady demand. Producers report that contracts are being effected on that basis.

Transportation facilities are better just at present than they have been at any time since the war, there being no difficulty in getting shipments of the raw materials and in shipping out the finished products on schedule time.

Demand for the 66 deg. *sulphuric acid* is steady and prices are holding well. This is a slight improvement over the situation two weeks ago and is the turn of the market that producers had been expecting. There is still evidence that the oil refineries are buying on a basis of present needs. Prices on the 66 deg. acid are \$24 per ton and 13c. per lb. in carboys in carload lots. Not much activity is shown in the market for 98 deg. *sulphuric acid* and it is quoted at \$25 per ton, f.o.b. works. The 60 deg. acid holds firm at the advanced price reported two weeks ago of \$16.50 per ton and 14c. per lb. in carboys. *Oleum* also retains the advance noted previously and is in good demand. The price is \$28.50 per ton.

Stocks of *muratic acid* are still large and demand is a trifle slow. It is quoted at 2@24c. per lb. in carboys in carload lots and \$25 per ton in bulk.

The demand for *sodium bisulphate* is steady and there is a large supply in producers' hands. The price is \$5@56 per ton. It is a question whether a quieter steel market may not have some effect on this chemical.

The market for *nitric acid* continues to show strength, but prices remain the same and deliveries are good. The quotations are \$7 per cwt. on the 36 deg. and \$10 per cwt. on the 42 deg. *Standard mixed acid* at 14c. per lb. for both the 36 deg. nitric and 61 deg. *sulphuric* is holding steady.

Zinc chloride continues to be quoted \$4 per cwt. *Phenol* is quiet at 12c. in lots of 15 tons or more.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

Ammonium nitrate.....lb.	.11 - .12	.11 - .14
Ammonium sulphate.....lb.	.07 - .07 1/2	.08 1/2 - .09
Amylacetate.....gal		4.50 - 5.00
Amylacetate, tech.....gal		4.00 - 4.20
Arsenic, oxide, lumps (white arsenic).....lb.	.13 - .14	.15 - .16
Arsenic, sulphide, powdered (red arsenic).....lb.	.16 - .17	.18 - .19
Barium chloride.....ton	120 - 130.00	
Barium dioxide (peroxide).....lb.	.24 - .25	.27 - .28
Barium nitrate.....lb.	.12 - .12 1/2	.13 - .13 1/2
Barium sulphate (precip) (blanc fixe).....lb.	.04 1/2 - .05	.05 1/2 - .06
Bleaching powder (see calcium hypochlorite).....lb.		
Blue vitriol (see copper sulphate).....lb.		
Borax (see sodium borate).....lb.		
Bromine (see sulphur, roll).....lb.		
Bromine.....lb.	.70 - .80	.85 - .90
Calcium acetate.....cwt.	3.50 - 3.55	
Calcium carbide.....lb.	.04 - .04 1/2	.04 1/2 - .05 1/2
Calcium chloride, fused, lump.....ton	30.00 - 32.00	33.00 - 35.00
Calcium chloride, granulated.....lb.	.02 - .02 1/2	.03 - .03 1/2
Calcium hypochlorite (bleaching powder).....cwt.	7.25 - 7.50	8.00 - 8.50
Calcium peroxide.....lb.		1.50 - 1.70
Calcium phosphate, monobasic.....lb.		.75 - .80
Calcium sulphate, pure.....lb.		.25 - .30
Carbon bisulphide.....lb.	.08 - .09	.10 - .11
Carbon tetrachloride, drums.....lb.	.13 - .14	.16 - .17
Carbonyl chloride (phosgene).....lb.		1.25 - 1.50
Caustic potash (see potassium hydroxide).....lb.		
Caustic soda (see sodium hydroxide).....lb.		
Chlorine, gas, liquid-cylinders (100 lb.).....lb.	.09 - .09 1/2	.10 - .10 1/2
Chloroform.....lb.	.40 - .43	.44 - .47
Cobalt oxide.....lb.		2.00 - 2.05
Copperas (see iron sulphate).....lb.		
Copper carbonate, green precipitate.....lb.	.27 - .28	.29 - .31
Copper cyanide.....lb.		.65 - .70
Copper sulphate, crystals.....lb.	.07 1/2 - .08	.08 1/2 - .09
Cream of tartar (see potassium bitartrate).....lb.		
Epsom salt (see magnesium sulphate).....lb.		
Ethyl Acetate Com. 85%.....gal.		1.05 - 1.10
Ethyl Acetate pure (acetic ether 98% to 100%).....gal.		
Formaldehyde, 40 per cent (nominal).....lb.	.40 - .45	
Fusel oil ref.....gal.		5.25 - 6.00
Fusel oil, crude (nominal).....gal.		
Glauber's salt (see sodium sulphate).....lb.		
Glycerine, C. P. drums extra.....lb.		.26 1/2 - .28 1/2
Iodine, resublimed.....lb.	4.30 - 4.35	4.40 - 4.45
Iron oxide, red.....lb.		.03 - .04
Iron sulphate (copperas).....cwt.	2.00 - 2.25	2.35 - 2.75
Lead acetate, normal.....lb.		.13 1/2 - .16
Lead arsenate (paste).....lb.	.11 - .12	.13 - .17
Lead nitrate, crystals.....lb.		.90 - 1.00
Litharge.....lb.	.14 - .15	.15 1/2 - .16
Lithium carbonate.....lb.		1.50 - 1.60
Magnesium carbonate, technical.....lb.	.12 - .13 1/2	.14 - .15
Magnesium sulphate, U. S. P.....100 lb.	3.00 - 3.25	
Magnesium sulphate, commercial.....100 lb.		3.50 - 3.60
Methanol, 95%.....gal.		2.70 - 3.00
Methanol, pure.....gal.		3.40 - 3.60
Nickel salt, double.....lb.		.14 - .16
Nickel salt, single.....lb.		.13 - .14
Phosgene (see carbonyl chloride).....lb.		
Phosphorus, red.....lb.	.50 - .55	.60 - .65
Phosphorus, yellow.....lb.		.35 - .37
Potassium bichromate.....lb.	.34 - .36	.39 - .40

	Carlots	Less Carlots		Carlots	Less Carlots
Potassium bitartrate (cream of Tartar)	lb. \$0.48 - \$0.56	\$0.57 - \$0.58	Para-nitrotoluene	lb. 1.25 - 1.40	
Potassium bromide, granular	lb. .50 - .55	.63 - .65	Para-phenylenediamine	lb. 2.50 - 2.65	
Potassium carbonate, U. S. P.	lb. .20 - .21	.23 - .25	Para-toluidine	lb. 2.00 - 2.25	
Potassium chlorate, crystals	lb. .18 - .18	.19 - .20	Phthalic anhydride	lb. .60 - .70	
Potassium hydroxide (caustic potash)	lb. .23 - .25	.26 - .27	Phenol, U. S. P., drums (dest.), (240 lb.)	lb. .11 - .20	
Potassium iodide	lb. .32 - .36	3.20 - 3.30	Pyridine	gal. 2.00 - 3.50	
Potassium nitrate	lb. .17 - .17	.19 - .21	Resorcinol, technical	lb. 4.25 - 4.50	
Potassium permanganate	lb. .63 - .68	.70 - .75	Resorcinol, pure	lb. 6.25 - 6.75	
Potassium prussiate, red	lb. .85 - .95	1.00 - 1.05	Salicylic acid, tech., in bbls. (110 lb.)	lb. .45 - .50	
Potassium prussiate, yellow	lb. .32 - .36	.35 - .40	Salicylic acid, U. S. P.	lb. .45 - .50	
Potassium sulphate (powdered)	ton \$240.00 - 255.00		Salol	lb. .85 - .95	
Rochelle salts (see sodium potas. tartrate)			Solvent naphtha, water-white, in drums, 100 gal	gal. .30 - .35	
Sal ammoniac (see ammonium chloride)			Solvent naphtha, crude, heavy, in drums, 100 gal	gal. .20 - .26	
Salt soda (see sodium carbonate)			Sulphanilic acid, crude	lb. .32 - .35	
Salt cake	ton 48.00 - 50.00		Toluidine	lb. 1.70 - 2.50	
Silver cyanide (nominal)	oz. 1.25 - 1.25		Toluidine, mixed	lb. .45 - .55	
Silver nitrate (nominal)	oz. .60 - .62		Toluene, in tank cars	gal. .35 - .40	
Soda ash, light	100 lb. 2.25 - 2.50		Toluene, in drums	gal. .38 - .40	
Soda ash, dense	100 lb. 2.25 - 2.50		Xyldines, drums, 100 gal.	lb. .50 - .65	
Sodium acetate, U. S. P., granular	lb. .25 - .26		Xylene, pure, in drums	gal. .47 - .50	
Sodium bicarbonate	100 lb. 2.50 - 2.75		Xylene, pure, in tank cars	gal. .45 - .50	
Sodium bisulphate (sulfur cake)	lb. .22 - .24		Xylene, commercial, in drums, 100 gal	gal. .12 - .15	
Sodium bisulphate powdered, U. S. P.	lb. .06 - .07				
Sodium borate (borax)	lb. .09 - .10				
Sodium carbonate (soda)	100 lb. 2.00 - 2.10				
Sodium chloride	lb. .14 - .15				
Sodium cyanide, 96-98 per cent.	lb. .2 - .30				
Sodium fluoride	lb. .18 - .20				
Sodium hydroxide (caustic soda)	100 lb. 4.00 - 4.25				
Sodium hypsulphite	lb. .03 - .04				
Sodium molybdate	lb. 2.50 - 3.25				
Sodium nitrate	100 lb. 3.00 - 3.75				
Sodium nitrite	lb. .11 - .12				
Sodium peroxide, powder	lb. .32 - .35				
Sodium phosphate, dibasic	lb. .03 - .04				
Sodium potassium tartrate (Rochelle salts)	lb. .37 - .38				
Sodium prussiate, yellow	lb. .25 - .27				
Sodium silicate, solution (40 deg.)	lb. .01 - .01				
Sodium silicate, solution (60 deg.)	lb. .02 - .03				
Sodium sulphate, crystals (Glauber's salt)	wt. 2.15 - 2.50				
Sodium sulphide, crystal, 60-62 percent (cone)	lb. .09 - .10				
Sodium sulphite, crystals	lb. .04 - 0.4				
Strontium nitrate, powdered	lb. .15 - .18				
Sulphur chloride, red	lb. .08 - .09				
Sulphur, crude	ton 16.00 - 20.00				
Sulphur dioxide, liquid, cylinders	lb. .09 - .10				
Sulphur (sublimed), flour	100 lb. 3.70 - 4.35				
Sulphur, roll (brimstone)	100 lb. 3.40 - 3.90				
Tin bichloride, 50 per cent.	lb. .13 - .14				
Tin oxide	lb. .55 - .55				
Zinc carbonate, precipitate	lb. .16 - .18				
Zinc chloride, gran.	lb. .13 - .13				
Zinc cyanide	lb. .45 - .49				
Zinc dust	lb. .12 - .13				
Zinc oxide, U. S. P.	lb. .17 - .25				
Zinc sulphate	lb. .03 - .03				

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb. \$1.25 - \$1.35	
Alpha-naphthol, refined	lb. 1.50 - 1.60	
Alpha-naphthylamine	lb. .45 - .50	
Aniline oil, drums extra	lb. .27 - .30	
Aniline salts	lb. .33 - .34	
Anthracene, 80% in drums (100 lb.)	lb. .90 - 1.00	
Benzaldehyde (f.f.o.)	lb. 2.00 - 2.10	
Benzidine, base	lb. 1.25 - 1.30	
Benzidine sulphate	lb. 1.05 - 1.15	
Benzoic acid, U. S. P.	lb. .85 - .90	
Benzoate of soda, U. S. P.	lb. .80 - .90	
Benzene, pure, water-white, in drums (100 p. l.)	gal. .35 - .40	
Benzene, 90% in drums (100 gal.)	gal. .33 - .38	
Benzyl chloride, 95-97%, refined	lb. .35 - .40	
Benzyl chloride, tech.	lb. .25 - .35	
Beta-naphthol benzene (nominal)	lb. 3.50 - 4.00	
Beta-naphthol, sublimed (nominal)	lb. .90 - .95	
Beta-naphthol, tech (nominal)	lb. .60 - .70	
Beta-naphthylamine, sublimed	lb. 2.25 - 2.40	
Cresol, U. S. P., in drums (100 lb.)	lb. .18 - .19	
Ortho-cresol, in drums (100 lb.)	lb. .23 - .25	
Cresylic acid, 97-99%, straw color, in drums	gal. 1.10 - 1.15	
Cresylic acid, 95-97%, dark, in drums	gal. 1.05 - 1.10	
Cresylic acid, 50% first quality, drums	gal. .65 - .75	
Dichlorobenzene	lb. .07 - .10	
Dimethylaniline	lb. 1.50 - 1.60	
Dinitrobenzene	lb. .90 - 1.00	
Dinitrochlorobenzene	lb. .30 - .37	
Dinitrofluorobenzene	lb. .32 - .35	
Dinitronaphthalene	lb. .45 - .55	
Dinitrophenol	lb. .40 - .45	
Dinitrotoluene	lb. .38 - .40	
Dip oil, 25%, tar acids, car lots, in drums	gal. .38 - .40	
Diphenylamine (nominal)	lb. .80 - .85	
H-acid (nominal)	lb. 1.75 - 1.85	
Meta-phenylenediamine	lb. 1.25 - 1.30	
Monochlorobenzene	lb. .18 - .20	
Monomethylaniline	lb. 2.00 - 2.40	
Naphthalene, crushed, in bbls. (250 lb.)	lb. .12 - .14	
Naphthalene, flake	lb. .10 - .11	
Naphthalene, balls	lb. .17 - .19	
Naphtholonic acid, crude	lb. .75 - .85	
Nitrobenzene	lb. .12 - .15	
Nitronaphthalene	lb. .40 - .50	
Nitro-toluene	lb. .18 - .25	
Ortho-amidophenol	lb. 3.25 - 4.25	
Ortho-dichlor-benzene	lb. .15 - .20	
Ortho-nitro-phenol	lb. .80 - .85	
Ortho-nitro-toluene	lb. .25 - .38	
Ortho-toluidine	lb. .35 - .40	
Para-amidophenol, base	lb. 2.50 - 3.00	
Para-amidophenol, HCl	lb. 2.50 - 3.00	
Para-dichlorobenzene	lb. .08 - .10	
Paranitroaniline	lb. 1.10 - 1.15	

Para-nitrotoluene	lb. 1.25 - 1.40	
Para-phenylenediamine	lb. 2.50 - 2.65	
Para-toluidine	lb. 2.00 - 2.25	
Phthalic anhydride	lb. .60 - .70	
Phenol, U. S. P., drums (dest.), (240 lb.)	lb. .11 - .20	
Pyridine	gal. 2.00 - 3.50	
Resorcinol, technical	lb. 4.25 - 4.50	
Resorcinol, pure	lb. 6.25 - 6.75	
Salicylic acid, tech., in bbls. (110 lb.)	lb. .45 - .50	
Salicylic acid, U. S. P.	lb. .45 - .50	
Salol	lb. .85 - .95	
Solvent naphtha, water-white, in drums, 100 gal	gal. .30 - .35	
Solvent naphtha, crude, heavy, in drums, 100 gal	gal. .20 - .26	
Sulphanilic acid, crude	lb. .32 - .35	
Toluidine	lb. 1.70 - 2.50	
Toluidine, mixed	lb. .45 - .55	
Toluene, in tank cars	gal. .35 - .40	
Toluene, in drums	gal. .38 - .40	
Xyldines, drums, 100 gal.	lb. .50 - .65	
Xylene, pure, in drums	gal. .47 - .50	
Xylene, pure, in tank cars	gal. .45 - .50	
Xylene, commercial, in drums, 100 gal	gal. .12 - .15	
Xylene, commercial, in tank cars	gal. .10 - .15	

Waxes

Prices based on original packages in large quantities

Beeswax, refined, dark	lb. \$0.30 - \$0.32	
Beeswax, refined, light	lb. .34 - .37	
Beeswax, white pure	lb. .52 - .61	
Carnauba, No. 1 (nominal)	lb. .90 - .95	
Carnauba, No. 2, regular (nominal)	lb. .75 - .80	
Carnauba, No. 3, North Country	lb. .75 - .76	
Japan	lb. .18 - .20	
Montan, crude	lb. .12 - .14	
Paraffine wax, crude match wax (white) 105-110 m. p.	lb. .09 - .09	
Paraffine wax, crude, scale 124-126 m. p.	lb. .09 - .10	
Paraffine wax, refined, 118-120 m. p.	lb. .11 - .11	
Paraffine wax, refined, 125 m. p.	lb. .12 - .12	
Paraffine wax, refined, 128-130 m. p.	lb. .13 - .15	
Paraffine wax, refined, 133-135 m. p.	lb. .16 - .17	
Paraffine wax, refined, 135-137 m. p.	lb. .17 - .18	
Stearic acid, single pressed	lb. .20 - .21	
Stearic acid, double pressed	lb. .22 - .23	
Stearic acid, triple pressed	lb. .24 - .25	

NOTE—Paraffine waxes very scarce

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lbs.

Pine oil, steam dist., sp. gr. 0.930-0.940	gal. \$1.00	
Pine oil, pure, dest. dist.	gal. 1.00	
Pine tar oil, ref., sp. gr. 1.025-1.035	gal. .48	
Pine tar oil, crude, sp. gr. 1.025-1.035 (tank cars f.o.b. Jacksonville, Fla.)	gal. .35	
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal. .85	
Pine tar, ref., thin, sp. gr. 1.080-1.090	gal. .36	
Turpentine, crude, sp. gr. 0.900-0.970	gal. 1.75	
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990	gal. .35	
Pine wood creosote, ref.	gal. .52	

Naval Stores

The following prices are f.o.b. New York, for carload lots

Rosin (H-D), bbl.	230 lb. \$12.90 -	
Rosin (E-I), bbl.	230 lb. 12.90 -	
Rosin (K-N), bbl.	230 lb. 12.90 -	
Rosin (W, G-W, W), bbl.	230 lb. 12.90 -	
Wood rosin, bbl.	230 lb. 12.90 -	
Spirits of turpentine	gal. 1.12 -	
Wood turpentine, steam dist.	gal. 1.22 -	
Wood turpentine, dest. dist.	gal. 1.18 -	
Pine tar pitch, bbl.	200 lb. 8.50 -	
Tar, kiln burned, bbl. (500 lb.)	500 lb. 14.50 - 15.00	
Reform tar, bbl.	500 lb. 15.00 - 15.50	
Rosin oil, first run	gal. .72 -	
Rosin oil, second run	gal. .75 -	
Rosin oil, third run	gal. .92 -	

Solvents

73-76 deg., steel bbls. (85 lb.)	gal. \$0.40	
70-72 deg., steel bbls. (85 lb.)	gal. .38	
68-70 deg., steel bbls. (85 lb.)	gal. .37	
V. M. and P. naphtha, steel bbls. (85 lb.)	gal. .29	

Crude Rubber

Para Upriver fine	lb. \$0.26 - \$0.26	
Upriver coarse	lb. .17 - .18	
Upriver can ho ball	lb. .17 - .18	
Plantation—First latex crepe	lb. .25 - .25	
Ribbed smoked sheets	lb. .24 - .24	
Brown crepe, thin, clean	lb. .22 - .22	
Amber crepe No. 1	lb. .22 - .22	

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls.	lb. \$0.16 - \$0.18	
Castor oil, AA, in bbls.	lb. .15 - .16	
China wood oil, in bbls. (f.o.b. Pac. coast)	lb. .16 - .16	
Cocanut oil, Ceylon grade, in bbls.	lb. .15 - .16	
Cocanut oil, Ceylon grade, in bbls. (nominal)	lb. .17 - .17	
Corn oil, crude, in bbls.	lb. .12 - .13	
Cottonseed oil, crude (f.o.b. mill)	lb. .10 - .11	
Cottonseed oil, summer yellow	lb. .13 - .14	
Cottonseed oil, winter yellow	lb. .13 - .14	
Linseed oil, raw, car lots (domestic)	gal. 1.07 -	
Linseed oil, raw, tank cars (domestic)	gal. 1.00 -	
Linseed oil, boiled, car lots (domestic)	gal. 1.09 -	

Olive oil, commercial.....	gal.	3.00	—	3.50
Palm, Lagos.....	lb.	.101	—	.102
Palm, bright red.....	lb.
Palm, Niger.....	lb.	.091	—	.10
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.101	—	.121
Peanut oil, refined, in bbls.....	lb.	.12	—	.18
Rapeseed oil, refined in bbls.....	gal.	1.30	—	1.45
Rapeseed oil, blown, in bbls.....	gal.	1.60	—	1.70
Soya bean oil (Manchurian), in bbls, N. Y.....	lb.	.14	—	.141
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.10	—	.11

FISH

Light pressed Menhaden.....	gal.	\$0.80	—	\$0.90
Yellow bleached Menhaden.....	gal.	.83	—	.84
White bleached Menhaden.....	gal.	.85	—	.87
Blown Menhaden.....	gal.	.90	—	1.00

Miscellaneous Materials

All f. o. b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$24.00	—	\$30.07
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	22.00	—	21.00
Barytes, crude, 88% to 94% ba., Kings Creek.....	net ton	10.00	—	12.00
Barytes, ground, f.o.b. St. Louis.....	net ton	26.50	—	28.00
Barytes, crude, first grade, Missouri.....	net ton	10.00	—
Blanc fixe, dry.....	lb.	.051	—	.06
Blanc fixe, pulp.....	net ton	60.00	—	60.00
Casein.....	lb.	.15	—	.18
Chalk, domestic, extra light.....	lb.	.05	—	.06
Chalk, domestic, light.....	lb.	.041	—	.051
Chalk, domestic, heavy.....	lb.	.04	—	.05
Chalk, English, extra light.....	lb.	.05	—	.07
Chalk, English, light.....	lb.	.05	—	.06
Chalk, English, dense.....	lb.	.041	—	.05
China clay, (Kaolin) crude, f.o.b. mines, Georgia.....	net ton	0.00	—	12.00
China clay (Kaolin) washed, f.o.b. Georgia.....	net ton	12.00	—	15.00
China clay (Kaolin) powdered, f.o.b. Georgia.....	net ton	18.00	—	22.00
China clay (Kaolin) crude f.o.b. Virginia points.....	net ton	8.00	—	12.00
China clay (Kaolin) ground, f.o.b. Virginia points.....	net ton	15.00	—	40.00
China clay (Kaolin), imported, lump.....	net ton	25.00	—	35.00
China clay (Kaolin), imported, powdered.....	net ton	30.00	—	60.00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	gross ton	8.00	—	14.00
Feldspar, crude, f.o.b. Maine.....	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine.....	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State.....	net ton	17.00	—	21.00
Feldspar, ground f.o.b. Baltimore.....	net ton	27.00	—	30.00
Fuller's earth, granular, f.o.b. Fla.....	net ton	25.00	—
Fuller's earth, powdered, f.o.b. Fla.....	net ton	18.00	—
Fuller's earth, imported, powdered.....	net ton	35.00	—	40.00
Graphite, crucible, 90% carbon, Ashland, Ala.....	lb.	—	.09
Graphite, crucible, 85% carbon, Ashland, Ala.....	lb.	.07	—	.09
Graphite, higher lubricating grades.....	lb.	.11	—	.40
Pumice stone, imported, lump.....	lb.	.04	—	.50
Pumice stone, domestic, lump.....	lb.	.06	—
Pumice stone, ground.....	lb.	.04	—	.07
Quartz (acid tower) fist to head, f.o.b. Baltimore.....	net ton	—	10.00
Quartz (acid tower) 1 1/2 to 2 in., f.o.b. Baltimore.....	net ton	—	14.00
Quartz (acid tower) rice, f.o.b. Baltimore.....	net ton	—	12.00
Quartz, lump, f.o.b. North Carolina.....	net ton	5.00	—	7.50
Shellac, orange fine.....	lb.	—
Shellac, orange superfine.....	lb.	1.05	—	1.10
Shellac, A. C. garnet.....	lb.	.90	—	.95
Shellac, T. N.....	lb.	.85	—	.95
Soapstone.....	ton	15.00	—	25.00
Talc, paper-making grades, f.o.b. Vermont.....	ton	12.00	—	22.00
Talc, roofing grades, f.o.b. Vermont.....	ton	9.50	—	15.00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Connecticut

JEWETT CITY—The Flisk Rubber Co., Chicopee Falls, Mass., plans to build a large rubber plant. B. Allen, 52 Vanderbilt Ave., New York City, engr.

Illinois

CHICAGO—The Sanitary Dist. of Chicago, 910 South Michigan Ave., has awarded the contract for the construction of the Calumet sewage treatment plant, to T. J. Forschner Const. Co., 125th and Michigan Ave., \$4,900,627.

KEWANEE—The city is having plans prepared for the installation of intercepting sewers, tanks and sprinkling filters. Estimated cost, \$250,000. Alvord & Burdick, 8 South Dearborn St., Chicago, engr. Noted May 12.

Kansas

NEWTON—Bethel College is having plans prepared for the construction of two 3-story, 85x160-ft. buildings, including a science hall, etc. Estimated cost, \$400,000. Lorentz Selnick & Co., 121 North Market St., Wichita, archts.

Maryland

BALTIMORE—The Church House and Infirmary, Bway, and Fairmont Ave., plans to build a 6-story addition to the hospital. A chemical laboratory will be installed in same. Estimated cost, \$600,000. Wyatt & Nolting, 1012 Keyser Bldg., archts.

Michigan

TRENTON—The city engaged C. W. Hubble, engr., 2348 Penobscot Bldg., Detroit, to prepare plans and submit estimates for the construction of water main extensions and filtration plant. The plans include the construction of a filter bed, etc.

Minnesota

DULUTH—J. T. McNicholas, Bishop, has awarded the contract for the construction of a 2-story, 150x150-ft. school on 28th Ave. East and 5th St., to McLeod & Smith, Sellwood Bldg., at \$396,300. Chemical laboratory equipment will be installed in same.

DENVILLE—A. R. Hollenberg clk of the Bd. Educ., will receive bids until Dec. 1 for the construction of a 2-story, 90x240-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$300,000. Croft & Boerner, Lonsdale Bldg., Duluth, archts and engr.

ST. PAUL—The Diocese of St. Paul is conducting a campaign to raise \$5,000,000 for schools and colleges. The building plans include the construction of a science hall, etc., at the college of St. Thomas, Mernan Park.

New Jersey

METUCHEN—D. Wortman, archt. and engr., 116 Lexington Ave., New York City, will receive bids until Dec. 1 for the construction of a 1- and 2-story addition to the factory for the General Ceramics Co., 50 Church St., New York City. Estimated cost, \$400,000.

New York

BEDFORD HILLS—L. F. Pilcher, State Archt., Capitol, Albany, has awarded the contract for the construction of a filtration plant at the New York State Reformatory here, to M. J. Launder, 199 South Lexington Ave., White Plains. Estimated cost, \$6,500.

BUFFALO—The Angola Tire & Rubber Co., 270 North Division St., has awarded the contract for the construction of a 2-story, 50x96x126-ft. addition to its factory, to J. A. Zoll, 398 Bird Ave. Estimated cost, \$55,000.

North Carolina

GREENSBORO—The Armour Fertilizer Co. has awarded the contract for the construction of a 1-story, 80x180-ft. fertilizer

and storage building, to the Austin Co., Bulletin Bldg., Philadelphia. Estimated cost, \$150,000.

Ohio

CLEVELAND—The Cleveland Steel Barrel Co., 9619 Meech Ave., has awarded the contract for the construction of a 1-story, 60x120-ft. factory at 9700 Meech Ave., to R. Hansen, 9723 Sandusky Ave. Estimated cost, \$25,000.

MTAMISBURG—The Bd. Educ. will soon award the contract for the construction of a 2-story, 84x92-ft. grade school. Estimated cost, \$125,000. F. L. Packers, New Hayden Bldg., Columbus, archt.

WEST PARK—The Bd. Educ. plans to build a 3-story high school. A chemical laboratory will be installed in same. Estimated cost, \$1,000,000. F. W. Featherstone, clk.

Oklahoma

TULSA—The city is having preliminary plans prepared for the construction of 6 additional filter units, etc. Estimated cost, \$350,000. Halway Eng. Co., 230 Lynch Block, engr.

WAYNOKA—The city plans an election in November to vote on \$60,000 bonds for the construction of a sewage disposal plant. H. S. Olmsted & Co., 117 Exch. Bldg., Oklahoma City, engr.

Pennsylvania

HATBORO—The Roberts and Mandor Stove Co., 11th and Washington Sts., Philadelphia, has awarded the contract for the construction of a 1-story, 60x100-ft. addition to its foundry, to the Austin Co., Bulletin Bldg., Philadelphia.

PHILADELPHIA—The General Carbonic Co., 847 North 3rd St., has awarded the contract for altering the 1-story factory and boiler house, to the Austin Co., Bulletin Bldg. Estimated cost, \$10,000.

PHILADELPHIA—The Philadelphia Dyeing & Finishing Co., Frankford and Vandike Sts., is having plans prepared for the construction of a factory on Torresdale St. Chemical equipment for the manufacture of dyes will be installed in same. Estimated cost \$50,000. M. Ward Easby, Crozer Bldg., archt.

UNIONVILLE—The Consolidated Bd. Educ., East and West Marlboro, Newlin and Pocopson, is having preliminary plans prepared for the construction of a 2-story vocational school here. A chemical laboratory will be installed in same. Estimated cost, \$100,000. Ritter & Shay, North Amer Bldg., Philadelphia, archts and engr.

Virginia

QUANTICO—The Bureau of Yards & Docks, Navy Dept., Wash., D. C., plans to build an incinerator plant to include a septic tank, etc., at the marine barracks, here.

West Virginia

BLUEFIELD—The Baptist Educ. Comm. plans to build 18 buildings, including a science hall, etc. Estimated cost, \$750,000.

Wisconsin

FOND DU LAC—The Fond du Lac Paper Co., c/o Morris Green, 298 Forest Ave., plans to build a 1- and 2-story, 100,000-sq-ft paper board factory on the shore of Lake Winnebago. Estimated cost, \$100,000.

MAYVILLE—The Free High School Dist. plans to construct a 60x280 ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$200,000.

MILWAUKEE—The Red Star Yeast Co., 27th and St. Paul Aves., has awarded the contract for the construction of a 2-story, 50x95-ft. yeast manufacturing building, to E. Steigerwald & Co., 3607 Vilet St. Estimated cost, \$30,000.

PLYMOUTH—The Plymouth Pdry & Machine Co., has awarded the contract for the construction of a 1-story, 150x162-ft. foundry and machine shop on Stafford St., to M. Runge Main St. Estimated cost, \$100,000.

SHEBOYGAN—The Vollrath Co., 13th and Michigan Aves., has awarded the contract for the construction of a 1-story, 180x200-ft. stamping shop for an enamel-ware manufacturing plant on Michigan Ave., to the D. P. Robinson Co., 61 Bway., New York City. Estimated cost, \$100,000.

WAUWATOSA—The Aromatic Chemical Co., 61st and Motor Ave., plans to rebuild its 2-story, 60x100-ft. chemical factory on Motor Ave., which was recently destroyed by fire.

WAUWATOSA—The city has awarded the contract for remodeling the sewage disposal plant, to the Kroening Constr. Co., Majestic Bldg., Milwaukee. Estimated cost, \$27,252.

Ontario

LONDON—The city plans to develop the sulphur well by constructing a plant for purifying the water and removing the sulphur. Estimated cost, \$30,000. H. V. Buchanan, Pub. Utilities Bd., London, engr.

MIDLAND—The city has appointed E. A. James & Co., engr., 38 Toronto St., Toronto to prepare plans for sewer extensions. A sewage disposal plant will probably be installed. Estimated cost, \$100,000.

NIAGARA FALLS—The Oneida Community Co. has awarded the contract for the construction of a 1- and 2-story manufacturing building, to Bancroft Jones Co. and for flushing and heat treating buildings to Norman McLeod, Kent Bldg., Toronto. Estimated cost, \$200,000.

SMOOTH ROCK FALLS—The Matagamit Pulp & Paper Co. has awarded the general contract for the construction of a 2-story pulp mill and store buildings, to Carter, Halls Aldinger Co., Union Bank Bldg., Winnipeg. Estimated cost, \$490,000.

ST. CATHARINES—The Bd. Educ. plans to build a 3-story collegiate institute. A physical and chemical laboratory including equipment will be installed in same. Estimated cost, \$400,000.

TORONTO—The Dominion Envelope & Carton Co., 150 Duchess St., has purchased a 7-acre site at Eastern Gap and plans to build a 1-story, 300x500-ft. envelope and paper box factory on same. Estimated cost, \$500,000.

TORONTO—The Northern Aluminum Co., Sterling Rd., plans to build a plate mill here. Estimated cost, \$200,000. R. H. Prack, 50 Bay St., engr.

Industrial Notes

BRAW-KNOX Co., Pittsburgh, Pa., had an exhibit at the American Foundrymen's Association exhibition, held at Columbus, O., Oct. 4 to 8, consisting of alarmshell buckets, water cooled furnace appliances and Prudential steel buildings.

THE H. H. ROBERTSON Co., Pittsburgh, Pa., announces the election of C. D. Mercer as vice-president in charge of sales. This occurred at the completion of Mr. Mercer's first year as sales manager of the company. W. S. Tallmann has been elected in charge of operation from Sept. 1. Mr. Tallmann will have charge of all factories, the tin reclamation, the traffic and purchasing departments. D. W. Jasper was appointed manager of the purchasing department, vice W. E. Coe, who resigned to go into the railway supply business with the Beck Hill Corp., New York City. Mr. Jasper joined the company June 1 and has been temporarily connected with the Pittsburgh district sales office.

FREY, BRASSERT & Co., engineers, Chicago, Ill., have been appointed consulting engineers for the Royal Netherlands Blast Furnace and Steel Works Co., The Hague, and plans and purchases are under way for the construction of two blast furnaces at IJmuiden, Holland. The plant is planned along American lines throughout, inclusive of furnaces, hot blast stoves, gas washing, ferro-concrete bins, charging, blowing and other equipment. The plant will be the first application of American practice in furnace lines, filling, blowing and general operation with Continental ores and cokes.

DYKSTRA & CHEMICALS, Inc., of St. Louis, Mo., has recently been organized and incorporated with a capital stock of \$10,000 to engage in the manufacture of dyestuffs and chemicals. Further information may be had from Joseph F. Kelly, 3023 Allen St., St. Louis, Mo.

THE MONSANTO CHEMICAL WORKS, St. Louis, Mo., has opened a Chicago office where a complete stock of the company's products is to be carried. V. L. Elmer, previously in charge of a division of the company's St. Louis sales department, will be in charge.

PIERCE & SKOGMARK, Inc., metallurgical and chemical engineers, formerly at 35 Nassau St., New York City, announce that they are now in the practice of engineering work with L. J. Summers & Co., 110 Nassau St., New York.

THE FREDERICK ENGINEERING CO. has opened up a district sales office at 1247 Marquette Bldg., Chicago, under the management of Fred W. Gillette, who will have charge of the distribution of automatic stokers and steam jet ash conveyors in this territory.

THE ST. LOUIS CHAMBER OF COMMERCE, PRODUCTION BUREAU, is collaborating with Louis C. Chapman, consulting geologist, in the preparation of a report and survey of the minerals produced commercially in Missouri. The aim of the survey is to establish definite knowledge of the state's mineral resources.

AMERICAN ELECTRIC GRAPHITE MFG. CO., Toronto, O., has recently been incorporated with a capital stock of \$175,000. Victor M. Weaver is president and general manager, Alfred Whiteside secretary and treasurer, and Howard E. Ratsford technical director. The company has a factory two miles south of Toronto, O., at the site of the Calumet Sewer Pipe Co. It has 115 acres of coal land, with mining rights.

THE CHEMICAL EQUIPMENT CO., Chicago, Ill., has discontinued its Philadelphia agency, which was under control of Edward M. J. Eigel, and in order to better serve its customers has appointed the Filleton Engineers, Inc., 253 Broadway, New York, as New York district agents, and C. A. Murphy, Hurt Bldg., Atlanta, Ga., as Atlanta district agent.

THE AMERICAN STEAM CONVEYOR CORP., Chicago, Ill., announces a change in name, to the Conveyor Corporation of America. Clarence C. Brinley has been retained as Eastern manager of the trolley carrier dept. and will be attached to the New York office, 110 West 40th St. Mr. Brinley was formerly with Gifford-Wood Co. and during the war was conveyor engineer for the Air Nitrates Corp.

THE FREEMPORT CHEMICAL CO. plant, at Freemport, Tex., has been acquired by the Stauffer Chemical Co., San Francisco. General headquarters for the plant, under the new ownership, will be located in Houston. R. E. Demmon, of San Francisco, will be local manager. Refined sulphur in various forms is manufactured. The Freemport Chemical Co. is a separate organization from the Freemport Sulphur Co.

DANIEL M. LUBERS, industrial consulting engineer, announces the removal of his offices to 2015 East 65th St., Cleveland, O.

THE NATIONAL LIME ASSOCIATION announces the appointment of Major E. Holmes as manager of the chemistry department. Dr. Holmes is a graduate of Indiana University and a post-graduate of Cornell. His industrial experience has been broad and has included the technical control of factory products, development of new products, building and operation of plants, consulting work with department heads, and the direction of industrial research. Dr. Holmes' services are available to everyone interested in the chemical uses of lime.

C. W. HUNT ENGINEERING CORP. has been formed with offices at 113 Liberty St., New York City, for the purpose of handling all sales entailing engineering in connection with the Hunt products and all engineering services previously performed by C. W. Hunt Co., Inc.

THE AMERICAN ENGINEERING CO., Philadelphia, Pa., has opened a new office in Cincinnati, for the purpose of extending Taylor stoker representation and service. M. M. Masson is in charge of the office, at 207 Nave Bldg.

THE ELECTRIC FURNACE CONSTRUCTION CO., Philadelphia, Pa., announces the successful starting up of new Greaves-Eichells electric furnaces at the Vancouver Engineering Works, Vancouver, B. C., and the Sullivan Machinery Co., Claremont, N. H.

Manufacturers' Catalogs

THE EAGLE-PICHER LEAD CO., Chicago, Ill., has issued a booklet on Eagle-Picher Products.

THE JEFFREY MFG. CO., Columbus, O., calls attention to an attractive 128-page catalog, No. 267, on Jeffrey Machinery for Every Industry, issued by the Export Division. In the foreword it says: "The great saving in time and labor effected by the mechanical handling of materials in nearly every industry of the world, as illustrated in this

book, is proof that labor-saving machinery is of invaluable service in this day of modern method." Many photographs are given which have been selected for the purpose of making it possible to draw a parallel to similar operating conditions, while the tables of sizes have been given to make more comprehensive the magnitude of equipments shown.

THE GENERAL ELECTRIC CO., Schenectady, N. Y., is issuing Bull. 18701A, which supersedes Bull. 18701. This bulletin, on Insulating Compounds, presents the principal characteristics and effective adaptations of the wide field of insulating and coating materials in a practical manner. It gives the imperative factors in selection as well as data on black and clear baking and air-drying varnishes, baking and air-drying japans; double-boiled linseed insulating oils; stokers and shellacs; pothead, joint, coil filling, metal filling, impregnating and various sealing compounds; air-chute cement; priming and finishing paints, enamels, lacquers, etc. These several compounds include every form of coating, impregnating, bonding, filling and finishing all parts of electric apparatus and accessories, such as motor, transformer, and regulator coil windings, armatures, commutators, commutator rings, contactor connections, bushings for switches, etc., for waterproofing, insulating, rust prevention and durability. General information is also given on the application of compounds, on baking ovens, thinners, containers, etc.

THE MERRILL CO., San Francisco, Cal., has recently issued an attractive booklet on the Merco Norstrom Valve, explaining why "It Can't Stick, It Won't Leak, It's Always Lubricated." Copies of the catalog may be obtained from the eastern office of the company in the Monadnock Bldg., in Chicago.

THE A. H. SLOAN CO., Inc., Detroit, Mich., has issued Bull. 5-11, on Royer Flow Indicators. These are adaptable to measurement of steam, air, gases, water and a number of cases involving the measurement of chemicals such as bicarbonate of soda solution, saponified oils, cutting compounds, ammonia liquors, etc. The instrument was originally developed to control the lubricating oil in the main bearings of the turbine power plant installed in the Eagle patrol boat manufactured for the Government, and has since been adapted to chemical work. The construction of all types of meters is based on the Pilot tube principle. Its means of tabulated data and graph charts the readings taken by the operator are materially simplified. In measuring corrosive liquids an oil seal is sometimes provided to prevent the solution being measured from coming in actual contact with the steel parts, and the parts which in this case are impossible to protect are made from more metal or other alloy, depending on the chemical reaction encountered. Type C-200 and E-300 are especially adapted for conditions where the point of measurement is isolated from the point at which the actual reading is to be taken. The portable outfit Type T-200 is an evolution of the stationary type, with means for adjusting the impact tube when it becomes necessary to make a search or traverse from the point of average velocity in the line, also micrometer adjustment for slope to magnify the deflection in the manometer for velocities which are too low to produce a readable deflection in a vertical manometer.

HOLZ & CO., New York City, announces new bulletins on new and improved testing apparatus: Bull. 9, Amster Standardizing Boxes, for checking tensile and compressive loads of testing machines; Bull. 10, the Humphrey Static Notched-Bar Testing Machine, for the quantitative measurement of the brittleness and ductility of steel and other metals, yielding autographic record of the bending-angle bending-moment diagram; with automatic integrator for total energy absorbed in breaking the test piece; Bull. 11, the Eden-Foster Repeated Impact Testing Machine, for investigating the resistance of metals to fatigue produced by repeated stresses of low force; Bull. 11, Apparatus for Magnetic Analysis, designed by Dr. C. W. Burrows: the rail defectoscope, rod analyzer, wire analyzer and cable defectoscope.

HASTIAN-BLERRING CO., Chicago, Ill., has just received from the press its new catalog on "Reko Welding and Cutting Apparatus." Various details of torches and regulators will be found in this booklet, together with prices of complete equipment and accessories.

ARMSTRONG CORK CO., Pittsburgh, Pa., has issued a new publication, "Nonpareil Insulating Brick," a 72-page book on the insulation of high temperature industrial equipment, such as boilers, furnaces, stills, hot blast stoves, ovens, kilns, etc. While

dealing particularly with the description of Nonpareil brick and their uses the book is more than a catalog. The subject of heat insulation has been thoroughly studied from both the theoretical and practical standpoints, and the results here compiled contribute to make this book a really valuable and instructive treatise. It is conveniently divided into sections, each dealing with a particular type of industrial apparatus so that any one can readily find the data for the equipment in which he is especially interested. Operating records, with and without insulation, are given, actual dollars-and-cents savings demonstrated, and the economy and advantages to be secured by the use of Nonpareil brick described in a most interesting and convincing manner. The book is attractively and substantially bound and profusely illustrated. Its subject matter is of such vital importance to all industries employing high-temperature equipment that plant managers, superintendents and engineers will find it a valuable addition to the technical library.

THE CONNERSVILLE BLOWER CO., Connerville, Ind., has just issued a revised bulletin, No. 110, describing the Victor blowers which are being used in connection with heat-treating and annealing furnaces, forges and other installations where air is desired in small quantities and under medium pressures.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1920 meeting Dec. 27, 1920, to Jan. 1, 1921, at Chicago, Ill.

AMERICAN ASSOCIATION OF ENGINEERS will hold a meeting on employment and education in the Congress Hotel, Chicago, on Nov. 12.

AMERICAN CERAMIC SOCIETY will hold its annual meeting the week of Feb. 21, 1921, at Columbus, Ohio, with headquarters at the Deschler Hotel.

AMERICAN ENGINEERING COUNCIL of the Federated American Engineering Societies will hold a meeting Nov. 18 and 19, 1920, in Washington, D. C. Headquarters will be at the New Willard Hotel.

AMERICAN GAS ASSOCIATION will hold its second annual convention at the Hotel Pennsylvania, New York, Nov. 15 to 20.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its winter meeting at New Orleans, Dec. 6 to 9. Headquarters will be at the Hotel St. Charles.

AMERICAN MIXING CONGRESS will hold its next convention in Denver Nov. 15 to 19.

AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS' 1920 annual meeting will be held in the Engineering Societies' Building from Dec. 7 to 10 inclusive.

PHILADELPHIA SECTION, AMERICAN CHEMICAL SOCIETY, will hold its regular meeting Nov. 18 at the Engineers' Club, Philadelphia. Ellwood Hendrick will speak on "Relativity and Life."

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall national convention at Carnegie Music Hall, Pittsburgh, Pa., Nov. 10, 11 and 12.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: Nov. 5, Society of Chemical Industry; Nov. 19, American Chemical Society; Dec. 10, American Chemical Society, joint meeting with Society of Chemical Industry, American Electrochemical Society and Société de Chimie Industrielle; Jan. 7, American Chemical Society; Jan. 11, Society of Chemical Industry, Perkin Medal award; Feb. 11, American Electrochemical Society, joint meeting with Society of Chemical Industry, American Chemical Society and Société de Chimie Industrielle; March 11, American Chemical Society, Nichols Medal award; March 25, Society of Chemical Industry; April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry, and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

The Federation's Washington Meeting

AS THE TIME approaches for the first meeting of the Federated American Engineering Societies and American Engineering Council in Washington, D. C., Nov. 18, 19 and 20, it becomes increasingly evident that an event of more than ordinary importance is about to transpire. We have endeavored consistently to support these new organizations through constructive criticism and suggestions. Among other points we have emphasized what must be almost self-evident, namely, that the success of the Federation will depend largely upon the number of constituent societies which decide to join. Impressive as a large aggregate membership may be, it is not so vital to the ultimate success of the Federation as the number of individual society members scattered throughout the country. It is gratifying, therefore, to learn that twenty-two societies have definitely cast their lot with the Federation; that eight more are now voting on the proposal and probably will send delegates to Washington. It is now certain that sixty-two delegates will be present, and when the meeting is called to order it is likely that the aggregate membership will be 50,000. Representing as they do engineers of all classes from all parts of the United States the member societies will give to the Federation and Council a potential force in engineering affairs that has never been equaled. Just how this force will be utilized and in what direction it will be exerted will be evidenced very largely in the first meeting of these bodies. In common with all engineers, therefore, we shall follow the proceedings hopefully and with deepest interest.

Making Progress Through Cleavage

THE ether of space enjoys all the rights and privileges of an imaginary thing. It is as elusive as a postulate in theology, for sometimes we have it—and then again we haven't. Some good men need it every hour and, like Sir OLIVER LODGE, find it a medium for the manifestation of departed spirits, while ALBERT EINSTEIN seems to get along pretty well without it. We have considered ether as having 450 times the density of platinum, and matter as therefore composed principally of holes in the ether; we have also regarded it as so airy and diaphanous that its qualities are "beyond numbers" and therefore over in the domain which is referred to by Sir EVELYN DE LA RUE as infinity; and again we have declared it to be *nil*.

Now comes Professor L. ZEHNDER, who reports, in the *Berichte der deutscher physischen Gesellschaft* (vol. 21, pp. 118-25, 1919), a hypothesis in which the ether is a substance whose ultimate particles consist of extremely small, perfectly elastic "ether atoms." These particles possess weight like ordinary atoms, but are

relatively much smaller and have a velocity of the order of that of light. In spite of these enormous velocities every atom of an element has an ethereal envelope, and so has every molecule. Then Professor ZEHNDER concludes that electricity is the *heat* of ether, that light is the *sound* of ether, while electric potential corresponds to the *temperature* of ether. The electron he holds to be an aggregation of a definite number of ether atoms. The hydrogen atom he believes to be spherical, and to consist of a globular elementary atom of completely elastic substance, surrounded by an ether envelope which is not completely elastic, since it consists of ether atoms compressed together, thereby giving rise to the existence of damped oscillations and ether motions. His views of the properties of ether, of radioactivity and of the problem of spectral lines are discussed at length in the paper.

It was just about 2,500 years ago that DEMOCRITUS formulated his atomic theory. All things he declared to be made up of atoms, and atoms were small, full, incompressible, without pores and homogeneous. They differed, however, in form, in position and in magnitude.

It has taken us 2,500 years to divide atoms into nuclei and electrons, and now Professor ZEHNDER wants electrons divided into atoms of ether. We have no objection. And if these units of ether are to constitute electrons by means of aggregation, then we would like to carve a niche in the temple of immortality for ourselves by suggesting that the units of ether also shall consist of still smaller parts which shall be endowed with whatever properties are needed. It's curious how ultimate particles seem invariably predestined to further subdivision—if we only wait long enough. If the particles we imagine do not carry on their surface the qualities we need, all we have to do is to carve them up to get new surfaces that were not there before. It is perfectly reasonable to do this.

Now we wonder—just wonder—how long this cutting up business will continue! Study leads to observation, and observation leads to the discovery of new principles—and then we cut up the particles to explain the principles. It would appear that the end is yet afar off, for in the understanding of nature we are still little more than children. There is a great deal yet to be observed, and it may be that in the future as in the past our only explanation will be to cleave the theretofore ultimate particles.

Another discussion that bids fair to outlast the youngest of us is the postulate of ether. Is there such a thing, or isn't there? Perhaps it is just as well not to be certain about it; not to pin our faith too firmly on an opinion. There was the phlogiston theory that held us in bondage for nearly two centuries. It was disturbing to progress.

Cause and Remedy Of Fuel Shortage

OF COMMODITIES commonly employed in industry few if any have been as scarce as fuel. After selling for months at about ten times the price seen occasionally before the war, coal has become relatively plentiful in the market, but it is claimed that stocks in the hands of consumers are unusually light for the season of the year and that there is likely to be a severe "car shortage" this winter, producing a fresh and serious scarcity. Petroleum has been scarce and the outlook for future supplies is considered unpromising. Natural gas is being shut off from industries, to be conserved for domestic use, at the ascending prices domestic consumers are expected to pay gladly.

As to the relative importance of the three fuels, it may be mentioned that when comparison is made on the only basis possible, that of heat units shown by scientific tests, production in the past two or three years has been in approximately the following proportions: Coal, 85 per cent; petroleum, 11 per cent; natural gas, 4 per cent. Thus, apart from necessities of certain cases requiring a particular form of fuel, coal presents the great problem, from the mere viewpoint of the production of heat.

Why should the fuel problem jump to such great importance at this time? What is the matter? A long-range view furnishes the answer. The demand for fuel has increased so rapidly and continuously as to put it out of natural proportion. The sum total of human activity at any given time is so much. From decade to decade our population increases by about 20 per cent. The amount of work a man is willing to do in a day decreases instead of increases. Science and invention increase the man's efficiency, more than offsetting this, but leaving no great margin. The sum total of industrial results that the nation can accomplish probably increases by more than 25 per cent per decade, but it certainly does not increase by as much as 50 per cent. All lines of industrial activity, therefore, cannot increase by 50 per cent every decade. If circumstances favor one industry, it must be at the expense of some other industry.

Now look at coal. From a production of 320,072 tons in 1830 the output rose to six and one-half times as much in 1840, 2,070,039 tons. The next decade saw a multiplication by three and one-half, and it was not until 1850 to 1860 that there was merely a doubling. Every decennial year through 1890 saw more than a doubling. Then a doubling required a trifle over twelve years, to a time between 1902 and 1903. Next there was a doubling to a time between 1916 and 1917, or a 14-year interval.

A little industry can double all it likes, for it has a relatively inexhaustible field of men, materials and equipment from which to draw, but when an industry grows to such size as the coal industry it is another matter. People have other things to do than mine coal, and the railroads have a few other things to do besides hauling coal. The people would have no disposition to stop increasing their use of coal, if they could get it in any quantity desired and at prices to which they have been accustomed. The halt in the geometric progression had to be called some time, and now proves to be the time. The work put into the mining and transportation of coal cannot continue to increase much more rapidly than the sum total of our industrial accomplishment

increases. A collection of problems, in mining coal with less effort, in transporting fuel, heat or energy more efficiently and in consuming more economically, is therefore presented.

Seeing Ourselves as The Cubans Might See Us

CUBA is about the richest country in the world. It has grown so rich that its wealth has taken on no less than a comedy character. Nearly every city contains a curious monument, usually in the form of a dwelling, of some hallelujah bumpkin who struck it rich and wanted to inflict the fruits of his own uncultured imagination in architecture upon the eyes of all beholders. The sale of patent leather shoes for feet theretofore bare has broken all records. There has been a veritable storm of diamonds and rubies and champagne on the island. Thousands of big sparklers emblazon collarless shirts. Bleary-eyed passengers on returning to this country have found themselves shouting for prohibition as an unexpected rebound from their days of cheer in Havana. Then the price of sugar went down and they have had to declare a moratorium in Cuba. Our good neighbors have been blowing in their money, and now they're in trouble. So we purse our lips and sink our chins into our collars and shake our heads and declare that they should have been more saving and thus avoided their present vicissitudes.

But how much better off are we? Have we saved? Have we been provident? Have we avoided debt when we could do it? Not so much as to make a very deep impression. Last year the people of the United States spent two billion dollars in luxuries, according to a recent statement of the Commissioner of Internal Revenue. That's about \$20 a head, with wines and liquors cut out. We're still a long way off from "normalcy." The other day the writer of this stepped into an umbrella shop on Fifth Avenue to have a ferrule put on a stick. The price, which used to be twenty-five cents, was a dollar. "How much is that one?" we asked, pointing to one of dark wood that looked very plain and "conservative," as they call it. "That," said the clerk, "is \$29.50. You see, the band is solid gold. With silver bands they run down to \$15 or even \$11 or \$12." "And the price of that?" we asked, pointing to a plain one with no band at all. "This," said the clerk, taking it down and fondling it, "has been turned without taking the bark off, so you see what a beautiful grain it has under the varnish. It is a genuine malacca." "I see," said the visitor. "And how much is it?" "That stick is \$40." "Whew! It does seem dear, doesn't it?" "Huh!" exclaimed the salesman. "A stick like that will last you all your life!" The public may have struck against high prices, but everybody doesn't know it yet. There is still a lot of easy money floating around, and easy money isn't good for us. It is bad for children, and no matter how old foreigners may be, most of us, the people of the United States, are still children.

Now that election is over it is time to quit boasting about ourselves and calling those persons bad names who don't vote as we do. When we bear in mind that every factory, every store, every railroad, every undertaking in progress, every development, is built and made with saving, it is but fair and right that we consider how important savings are. Every bank loan is made up of money set aside and saved by somebody or bodies. All the skyscrapers in New York were built with money

that was earned and saved. So is every establishment, big and little, built with the savings of the promoter or the stockholders, or the mortgagor or the depositor with the mortgagor—or all of them.

It is high time that those of us who have a little influence began to set the example of saving and then to preach its virtues. Pretty soon the value of money will increase again and the value of commodities and work will decrease. Then it will be very hard for those who have saved nothing and very comforting for those who have been provident.

Is Soundness in Steel Sacrificed to Tonnage?

AS AMERICANS we are accustomed to bigness—high mountains, wide rivers, great lakes, mighty forests, and open country. Our business and industrial life seems to have been cast in this mold. Favored with tremendous resources of raw materials, our steel industry, as an instance, has grown to perfectly extraordinary proportions, far outstripping in volume that of any other country. Considerations as to size are somewhat commonplace—we, as Americans, rather expect our undertakings to be big; but are we not also dangerously complacent as to the quality of these stuffs we produce in such huge tonnages?

Steam traction was invented and perfected in the United States. We also make transverse-fissured rails—somehow, sometimes, no one knows why. Americans of ingenuity have designed fighting engines and defences of many types, yet when our steel men had to make them in quantity, a disease called “flakes” attacked the steel, and the doctors have not yet agreed upon the nature of the ailment, let alone proposed a specific. We build the biggest locomotives and the most automobiles, yet more lost time is chargeable to not quite good enough springs than to any other cause. Are we not more interested in volume of output than the excellence of the article in all its details?

Ten years ago there was a horrified outcry from the informed public about the deadly toll of rail failures, and spurred by this or their consciences, American steel makers turned anxious attention to their rail mills. Recent statistics show a most noteworthy improvement in service records; how this has been effected other than by careful attention to details has not been told, yet we suspect that even yet not enough attention is given toward producing sound ingots. Few would contest the statement, “a prerequisite to faultlessly finished material is perfect ingots”; fewer, unfortunately, have a realization that steel is very hot, is highly reactive, is delicate to handle, in fact is not *made*, until it has safely been cast into sound ingots.

But before venturing into a discussion of whether it is commercially possible to produce sound ingots it would be desirable to define the word “sound.” “Sound” metal to one may mean an ingot which will roll into a salable product; to another, it may mean a casting without surface flaw or interior cavity, free of chemical segregation and non-metallic inclusions. Both represent the views of extremists. The first is a pernicious byproduct of a period when manufacturing profits are big enough to cover avoidable and profligate waste. The second is a hallucination of a cub inspector, comparatively harmless, even if bothersome.

Soundness may therefore be recognized as a comparative term. Absolute homogeneity in solidified steel

is, by its very nature, impossible. Like most substances, it expands when it is heated and contracts on cooling; hot melted steel filling a mold to the brim will have considerably less volume when it has solidified, and consequently the mold will be full no longer. Hence pipes, contraction cavities and shrinkage cracks. It is idle to try to prevent the contraction demanded by nature's law; the best that can be done is so to control the formation of the resulting cavities that this type of defect is surely localized in a definite region.

Similarly, physical homogeneity is evidently impossible in a substance, like steel, solidifying over a wide range in temperature, by the fundamental law that a solid appearing from such a melt has a different composition than the mother liquor. Hence segregation. Even subsequent and drastic heat treatment which may be able to transport carbon over long distances is unable to equalize the distribution of slightly soluble or thoroughly insoluble substances such as sulphides or oxides—substances which are unquestionably normal constituents of steel, and doubtless always will be. Here again, by the very nature of things, the metallurgist is prevented from doing anything but so controlling natural laws that their effects will be felt in a predictable manner.

Despite these limitations, a definite and even precise conception may be had of the term “sound ingot metal.” For our purposes it shall mean metal which has been so made, cast and cropped that if split it will be found free from visible cavities or cracks, a chemical survey will not show segregation greater than say 12 per cent of the heat analysis, and a microscopic study will not show quantities of oxidized inclusions.

Future progress toward the “soundness” represented by this definition will come from close observation of the natural properties of fluid steel as modified by the shape and construction of the molds, especially at the head, the temperature and method of pouring, and to a lesser extent but not less essential, the composition of the metal. That Americans can go far in this direction is apparent to every thoughtful observer of existing conditions, which can only be described as scandalous. Whether due to a purchasing public which is helpless, ignorant or impassive, or to makers who have hypnotized themselves into thinking that sound products are really not essential, or if they are they can be worked from spongy ingots, the fact remains that vast tonnages of beams, plates, rails and other shapes are made of ingots which no one, not an extremist, would call “sound.” A steel salesman would also point out that this material is giving satisfactory service, and in the long run service is the master test. Satisfactory, *except* now and then! In rails alone these exceptions cause hundreds of casualties a year. Surely a weighty exception!

Rails are only an instance. That American metallurgists have suppressed their natural instincts for quality before production is at once a scandal and an indictment. Or is it that the “quantity-man” stands first in the eyes of big business? No matter. It was all very well as long as American steel was sold to Americans, who wanted trainloads of it cheap. But when the American market is saturated—and is it not becoming so?—big business will find it will have to make belated obeisance to the altar of quality, else the older worshipers from England and Continental Europe will romp off with all the foreign trade. Perhaps even the American public will become discriminating, if these pestiferous propagandists are not quieted somehow!

Gasoline Cracking Processes

Description of Commercial Methods for the Production of Gasoline by the Pyrolytic Distillation of Heavy Hydrocarbons, Including the Burton, Greenstreet, Hall, Rittman, Aluminum Chloride, Dubbs, Jenkins, and Bacon Processes—List of Inventors, Patent Numbers and Dates

By FRED W. PADGETT

IN A recent issue of this journal,¹ the phenomena of cracking of petroleum were discussed from their chemical aspects without regard to details involving the various commercial processes, which are the subject of the present paper. The writer does not wish to convey the impression that all the processes to be enumerated here are necessarily successful from a financial point of view, but they have in the main been used for the production of marketable gasoline.

The various processes for producing motor fuel from heavier hydrocarbons may be roughly classified as follows:

(1) *The Pressure Still.* A "two-phase" cracking system. Examples are the Burton and Coast processes.

(2) *The Pipe Still.* Generally a "one-phase" cracking system. Examples are the Greenstreet, Hall and Rittman processes.

(3) *The Use of Catalytic Agents at Atmospheric Pressure.* This may include reaction both in the "single-phase" and in the "two-phase" systems. An example is the aluminum chloride process, which is likely "two-phase" to some extent.

(4) *Combinations and Modifications of Two or More of the Above Methods.* The "cracking" may be in either "single-phase" or "two-phase" systems. Examples are the Dubbs, Jenkins and Bacon processes.

(5) *Processes Involving Principles Not Included Under the Above Four Headings, but Which May Involve Similar Apparatus or the Use of Pressure.* These methods may have either "single-phase" or "two-phase" cracking systems. Examples are the proposed processes of Cherry,² Coast,³ Ellis⁴ and many other processes, equally unique.⁵ In the first, a bipolar, high-voltage, oscillating, silent electric discharge is passed through the vapors; in the second, hot gases are passed through the oil or into contact with oil spray; and in the third, air is supplied to the cracking chamber, where, by combustion of a portion of the oil, the heat necessary for the "cracking" of the remainder is generated.

During the past eight years numerous patents involving almost every conceivable form of apparatus have been granted for the purpose of securing hydrocarbons within the gasoline range from those of higher boiling point. Many of these patents seek to obviate the trouble incident to coke deposition, while others have the object in view of producing a gasoline which is comparable

in quality with the natural product. Still others are along entirely new lines.

As early as 1865, James Young, a Scotch industrial chemist, secured a patent for the production of illuminating oil by means of pressure at about 20 lb. to the square inch.

The apparatus of Benton for the production of illuminating oils from residual oils was patented in 1886, but was never used commercially. A pipe coil within a furnace is heated to a suitable temperature while the oil is forced through at a pressure of 285 lb. or more to the square inch. The products of the reaction are released into a vapor chamber, which in turn is in communication with a condenser. At the inlet end of the coil is placed a safety valve and at the outlet a stop cock for regulating the pressure on the coil.

In 1890, a patent was granted *Dewar and Redwood* for an apparatus involving design different from that of Benton. The process was intended for use in cracking Russian residual oil to illuminating oil, but was never applied commercially because of the demand for the starting material as fuel and its consequent rise in price. A retort disposed in a furnace has one end in communication with a dome, the latter also being connected to a condenser. Safety valve, pressure gage, charging line and receiver are also shown, and the condenser and receiver are held under pressure. It is proposed to fill the retort partially, to distill under pressure and to collect the distillate in the receiver. Dewar and Redwood do not state what pressure gives the best results.

THE BURTON PROCESS

Burton's first patent was granted in 1913, and the process is extensively used at the present time by the various Standard Oil companies. In 1918 it was estimated that 10 per cent of the gasoline produced was by cracking, a large proportion of this being through Burton stills. The development of this process marks one of the milestones in the history of petroleum refining and its originator merits the distinction of being the first to demonstrate that pressure distillation could be done safely and practically on a large scale. In addition, Burton realized the limitations of the type of apparatus and did not attempt, in the original design, to make the operation continuous.

The original claims of Burton consisted in the distillation of petroleum under a pressure of 4 to 5 atmospheres and a temperature of 650-850 deg. F., maintaining the pressure upon the volatile products until they had passed through the condenser.

The standard Burton apparatus includes a still of 200-bbl. capacity or more, of conventional shape, so constructed that high pressures may be used. Modifications of the Burton process call for introduction

¹See CHEM. & MET. ENGR., vol. 23, No. 11, Sept. 15, 1920, p. 521.
²U. S. Pat. 1,229,886, Jan. 12, 1917, and U. S. Pat. 1,327,023, Jan. 6, 1920.

³U. S. Pat. 1,252,101, Jan. 8, 1918, and Cosden-Coast, 1,261,215, April 2, 1918.

⁴U. S. Pat. 1,295,825, Feb. 25, 1919.

⁵Some of the principles involved are as follows: The use of molten metal as a cracking agent; oil may be sprayed against an electrically heated plate within an autoclave; a perforated basket charged with metallic turnings may be disposed in a furnace; oil vapors may be subjected to progressively increasing and then progressively decreasing temperatures; superheated steam; various methods utilizing electric discharge across vapors; emulsified oil as starting material; etc.

of the oil in the vapor line,* amounting to semi-continuous operation, the use of false bottoms' upon which the main portion of the carbon collects, and lastly a still of the water tube boiler type.[†]

At the present time the Standard Oil Co. of Indiana is operating three types of pressure distillation apparatus: (1) The Burton-Humphreys still; (2) the Clark apparatus; and (3) a later improvement of the original Burton-Humphreys modification involving the use of a special tower through which the vapors proceed before entering the water-cooled condensers. The first is generally operated intermittently or "batch," the latter two "semi-continuously"—i.e., oil is pumped in to replace that removed by distillation.

The arrangement of the vapor lines and receiving houses is of interest. The vapor lines from the Burton-Humphreys stills ascend gradually, terminating in manifolds which in turn connect with aerial condensers. During operation, vapors liquefied in the aerial condensers are continuously being refluxed to the stills. The uncondensed vapors from the aerial condensers enter the water cooled coils, where liquefaction takes place accompanied to some extent by solution of permanent gases in the distillate passing through the coils. From each water-cooled coil a "run line" terminates in an upright drum (gauge glass at the side) which serves as a temporary receiver for the pressure distillate and also as a chamber for the separation of permanent gases not in solution in the distillate. A manifold constructed from small pipe connects together the tops of all the receiving drums in a battery of stills and serves the following important purposes: First, the equalization of pressure throughout the entire battery; second, the control of pressure on the stills in the battery (by means of a relief valve); and third, the withdrawal of permanent gases not in solution in the distillate.

The distillate in the receiving drums, consisting of from 50 to 60 per cent of the original charging material and yielding 50 to 55 per cent of gasoline upon subsequent fractionation in steam stills, is continuously withdrawn and collected in tanks at a pressure near that of the atmosphere. The gases which are produced during "venting" contain considerable quantities of gasoline vapor and may be treated by standard methods for gasoline recovery. The heavy residuum left after repeated "cracking" of the primary distillates heavier than gasoline and the primary residuums has a density approaching that of water and finds application as road oil.

It is claimed for the Burton process that by proper "rerunning" of primary residuum and heavy distillates in the pressure stills, 75 per cent of an oil, such as Oklahoma crude, may be recovered as gasoline. For obvious reasons, however, this is not the customary practice.

THE DESIGN AND OPERATION OF PRESSURE STILLS

At the temperature at which the pressure still operates steel begins to decrease in tensile strength. Therefore, it is evident that a fundamentally important consideration lies in the material and method of construction of the stills.[‡] As an outgrowth of this need there are now firms which specialize in the construction

of stills for severe usage.[§] The stills are solid metal $\frac{1}{2}$ to $\frac{3}{4}$ in. in thickness and hammer welded,^{||} this method of construction being claimed as superior to both riveting and to acetylene or electric welding, for the purpose in view. In the operation of pressure stills the operator has before him thermometers and pressure gages, which inform him of the conditions prevailing within the various units under his control.[¶] In the operation of some pressure stills using gas oil as the starting material, the distillation is continued at the average rate of 1 to 2 per cent an hour and the run is completed in 48 hours, giving a yield of 35 per cent of 450-deg. F. end point gasoline. During distillation the bottom of the still is watched if any "hot spots" develop, due to superheating from deposited carbon, and close surveillance is maintained to determine if it will be necessary to close down the still before the run is completed. After each run the deposited carbon is completely removed from the still before recharging.

During the operation of pressure stills, the proper distribution of heat on the bottoms of the still is important. Between operating periods it is customary to inspect the apparatus carefully at all points and often to measure the thickness of the metal so that the amount of corrosion, due to sulphur compounds in the oil, may be ascertained.

THE GREENSTREET PROCESS^{**}

The first patent in this process was granted to the applicant in 1912,^{††} and a plant of this design has been in operation in St. Louis for a number of years. By this method the oil vapors are subjected to heat while traversing tubes in the presence of steam. The oil to be treated is first forced through preheater coils so arranged in the furnace that a very high temperature is not secured. The oil is then mixed with steam and enters the cracking coils, where the vapors are subjected to the most severe temperature conditions in the entire cycle. From the cracking zone the products leave the coil and enter drums of considerable size where the velocity of the vapors is lessened, the heavier constituents condense, while cracking and polymerization continue for a longer time than otherwise would be the case. Leaving the expanding drums, the lighter vapors are reduced in pressure before they enter the condenser. The heavier products are drawn off from the bottom of the expanding drums.

THE DESIGN AND OPERATION OF PIPE STILLS FOR CRACKING

In the Greenstreet process the cracking coil units are of 2-in. pipe 425 ft. in length, six or more of which are arranged in the furnace to make up the complete installation. These coils are suspended from steel beams at the top of the furnace in a way that facilitates easy removal and replacement. The furnace is operated by a stillman who has before him gages, meters and thermometers for noting the conditions prevailing in the process. When operating pipe stills in the presence of steam^{‡‡} for the production of motor fuel from heavier hydrocarbons, the rate of flow, temperature, pressure and quantity of steam depend upon the character of the initial material. Thus kerosene would neces-

††English Patent, 16,452, July 13, 1912.

‡‡Private communication.

sitate the use of less steam, but a higher pressure and temperature, than gas oil, to secure the best results. In operating pipe stills for cracking, it is considered necessary to determine optimum operating conditions for a particular type of starting material, and then to adhere as strictly as possible to these conditions during subsequent runs. "Close cut" distillates are said to give the best results.

THE HALL PROCESS

Although developed by an American, this process was first tried on a commercial scale in the British Isles, being used throughout the war for the production of benzol and toluol from gas oil. In this country the Texas Company has been interested in the process and has done considerable research, but at this time has no information which it wishes to make public. The apparatus, in a broad way, resembles that of Greenstreet, but has the fundamental difference of operation in that steam is not used. The operation of one of Hall's British plants was described by Lomax in 1916, but since Hall has been a prolific inventor, especially on methods of treating the distillates secured, it is possible that important changes have been incorporated in the commercial operation since that time.

It has been reported that the Hall process is being used to "crack down" heavy Mexican crude to a suitable viscosity for use as fuel.

The oil traverses the coil and is gradually heated until the most severe conditions are encountered at the outlet where the pressure is reduced to near atmospheric, the speed of the vapors reaching 5,000 to 6,000 ft. per minute. From the expanding drum the vapors pass through a series of dephlegmators where several products of varying boiling point are removed and finally to a compressor where the vapors are compressed and then cooled. Each coil is composed of 600 ft. of cold-drawn 1-in. (internal diameter) tubing, and the coils are spoken of as being arranged in nests.

For the production of motor fuel a temperature of 550 deg. to 600 deg. C. obtains at the tube outlets (pressure, 75 lb.), but in working for benzol a temperature of 750 deg. C. and pressures of 100 to 105 lb. to the square inch are necessary. No doubt these conditions will vary for various types of starting materials. It is claimed that motor fuel to the extent of 70 per cent can be secured from the total original oil charged, by rerunning certain residues from the dephlegmators.

THE RITTMAN PROCESS¹

So many are familiar with the principles of this method that a detailed description is unnecessary here. Suffice it to say that the "cracking" takes place in the vapor form in an upright tube. Oil is atomized into the tube at the top and the gasoline vapors and tar are taken off separately from the tar pot at the bottom. Carbon is removed from the sides of the tube in the cracking zone by means of a rod and chain, the latter being thrown against the sides when the former is revolved. Optimum conditions for operation are given as follows by Rittman and Dean: for gasoline 500 to 550 deg. C. and a minimum of 12 atmosphere pressure; for the production of aromatics a temperature of 625 to 700 deg. C., and a minimum pressure of 8

atmospheres are recommended. A single tube of the Rittman type is specified by Bowie as 13 to 14 in. in diameter and 13.5 ft. in length.

THE ALUMINUM CHLORIDE PROCESS²

The most conspicuous developments under this method have been carried out by McAfee³ of the Gulf Refining Co. The oil is heated and stirred in a still in the presence of anhydrous aluminum chloride or other anhydrous salt of aluminum. Before treatment the oil must be freed from water and a quantity of the catalyst equal to a maximum of 8 per cent by weight of the oil charged is added before the distillation is begun. Fractionating towers are interposed between the still and the condenser so that the higher boiling vapors may be returned to the still along with aluminum chloride which has been vaporized and carried out. The distillation is continued slowly at a temperature of 500 to 550 deg. F. over a period of 24 to 48 hours. By this method, a yield of gasoline of 15 per cent or more may be obtained from residual oils.

Very interesting in connection with this process is the effect upon the residue remaining in the still and the character of the distillate secured. At the end of the distillation it is found that the aluminum chloride is enclosed in granular coke, which is easily removed, and that a heavy oil free from asphalt, its viscosity in no way impaired by the procedure, may be separated from the coke and then utilized for the production of high-grade lubricating oils, the recovery of paraffine wax or the manufacture of petrolatum. The distillate secured by aluminum chloride treatment is water white, possesses a pleasant odor and in order to secure the finished gasoline it is only necessary to wash the "re-run" distillate with dilute alkali and water.

By the action of anhydrous aluminum chloride on residual petroleum, sulphur compounds are destroyed and possibly nitrogen and oxygen compounds such as naphthenic acids as well.

The one difficulty suggesting itself as being inherent in this process is that of recovering the aluminum chloride, or of manufacturing it cheaply.

OTHER PROCESSES

Three methods which have recently come into prominence because of favorable reports concerning their operations are those of Dubbs, Jenkins and Bacon.

The design and operation of the *Dubbs plant* is given in the report of a committee of the Western Refiners' Association to its members. Extracts from this report are quoted as follows: The plant proper consists of a cracking coil made up of ten lengths of 4-in. extra heavy lapwelded pipe, each 20 ft. in length, joined on the ends by return bends. This coil of 4-in. pipe is located horizontally in a furnace in two rows, six of the pipes being in the lower row and four in the upper row. The furnace temperature is maintained at approximately 1,540 deg. F. The outlet of the 4-in. coil is connected to an expansion chamber, which consists of four 20-ft. lengths of 10-in. common extra heavy pipe. These pipes are connected in series by return bends so as to form an expansion chamber approximately 80 ft. long. These 10-in. pipes are located horizontally in a chamber and are not heated, but lagged to prevent loss of heat by radiation.

¹Lomax, *J. Inst. Pet. Tech.*, vol. 3 (1916), p. 36.

²See U. S. Bureau Min. Bulletin 114 and Technical Paper 161.

³See *J. Ind. Eng. Chem.*, vol. 7 (1915), p. 737.

⁴*Ibid.*

The raw oil is fed into one end of the 4-in. coil by means of a force pump, and as the oil passes through, it is heated to about 820 deg. F. and is then discharged from the other end into the 10-in. expansion pipes, which are maintained approximately half full of oil. The vapors are liberated from the oil and pass up through connecting goosenecks to a manifold, then to vapor lines leading to a spiral vapor condenser and finally into a water-cooled condenser. A pressure of about 135 lb. to the square inch is maintained on the entire apparatus. The unvaporized portion of the oil in the 10-in. coil is continuously drawn off from the end of the last unit.

In regard to the Dubbs process, it should be noted that the "cracking" takes place in a "two-phase" system.

The results of a test run of 168-hr. duration are summarized as follows:

Total gas oil treated, gal.	20,952
Total uncondensable gas, cu.ft.	25,851
Fuel used ¹⁰ - equivalent of 3,677 gal. of 14 B ₆ fuel oil.	
Products (per cent yield of original oil charged):	Per Cent
Gasoline (440 end point), (58-59 deg. B ₆)	26 29
Kerosene (40-41 deg. B ₆)	14 11
Pressure distillate bottoms (31-32 deg. B ₆)	27 19
Residuum (13-14 deg. B ₆)	24 71
Loss	7 70

The principle of the *Jenkins process* is the use of an apparatus resembling the water-tube boiler. The tubes in the latest installation are 2½ in. outside diameter, and cold drawn. The furnace is of the vertical baffle type with Dutch oven, no heat coming in direct contact with either the longitudinal or transverse drums. The operation of the process is continuous and the oil is circulated mechanically. The safe limit of operation (with the type of starting material being used) has been found to be when a volume of oil equal to fourteen times the charging capacity has been passed into the apparatus. Working under these conditions, it is claimed that the life of the still is greatly prolonged and that the time of cleaning is five minutes per tube. In closing down after a run the reduction of temperature is accomplished gradually by forcing more charging oil into the apparatus under complete mechanical circulation, thus eliminating undue stresses or strains which might be caused by a sudden temperature drop. Mr. Jenkins contributes the following data in connection with a run of 46 hours, using pressure distillate gas oil¹⁰ from Homer crude as the starting material:

Total oil circulated, gal.	17,130
Overhead pressure distillate, gal.	11,600
Fuel used 48,000 cu ft. of city gas (natural).	
Products (per cent yield of original starting material):	Per Cent
Gasoline (118 t.b.p., 460 end point).	24
Kerosene	29
Steam still bottoms	14
Pressure still bottoms (52 vis. Saybolt at 100 deg. F. and when treated, 4-5 color)	27
Total loss	6

The pressure used in the above run varied from 105-110 lb. gage; temperature 700-710 deg. F.

THE BACON PROCESS

The Bacon process was developed under the direction of Raymond F. Bacon and Benjamin T. Brooks at the Mellon Institute of Industrial Research. As originally designed, some difficulties were encountered during operation because of coke deposition on the tubes but, according to the latest information, certain improvements have made the process appear very

promising. The "cracking" is carried out in vertical tubes 20 ft. in length and 6 to 19 in. in diameter, the oil level being maintained at the top of the heated zone, and the process operated continuously. The oil inlet and vapor outlet are located at the top of the tube. The lower ends of the tubes are connected to a drum into which the tar and coke settle and are drawn off from a pipe at the bottom. When operating an apparatus of this type, coke accumulates very slowly on the metal surface in the cracking zone and in addition a large heating surface is exposed to the oil. The pressure specified is from 60 to 300 lb. to the square inch, but preferably 100 lb. The yields of gasoline (56 B_é) claimed for various oils are as follows:

	Per Cent
Oklahoma gas oil (32 deg. B ₆)	45
Mexican fuel oil (12 deg. B ₆)	50
California fuel oil (14 deg. B ₆)	47
Caddo heavy crude (12-14 deg. B ₆)	48

THE PRESENT STATUS OF THE PETROLEUM "CRACKING" INDUSTRY

While the past eight years has seen an enormous amount of research and invention along this line, the present finds but few which may safely be designated as established processes. A conclusion which is soon reached is that no matter how promising a process may appear at the beginning, only extended plant operation determines its commercial success. The operation of the pressure still is approaching something like standard practice in many refineries, but even then has its limitations. Some time ago one optimistic refiner informed the writer that he had directed his research staff to bend its energies toward the discovery of a chemical agent, either catalytic or otherwise, which would transform all, or nearly all, of the heavy hydrocarbon mixture into gasoline, with only negligible loss due to coke and gas formation. However difficult this may be, such a course would seem to be the most legitimate in view of the results in the past ten years along other lines.

In the field of pure research it is desirable that the problem of the composition of petroleum be undertaken in a broad way and with sufficient funds and personnel to insure the solution of the problem within a reasonable time. In the past this work has been handicapped, not by the lack of expert or enthusiastic direction, but by the need of more extended facilities. Such routine work as fractional distillation consumes a great deal of time.

The need of research upon the properties of the higher members of the hydrocarbon series other than the aromatics has been emphasized by Brooks¹¹ and needs no discussion here.

Wave Power Transmission

FROM OUR LONDON CORRESPONDENT

London, Oct. 13, 1920.

The formulation of a new and practical method for the transmission of energy is a rare occurrence, and the announcement just made by W. H. Dorman & Co., Ltd., of Stafford, seems to be of far-reaching importance to the mining, shipbuilding and allied industries. The principles of the transmission of power by wave impulses through liquids were necessarily kept secret during the war owing to their use for the automatic firing of guns on airplanes and like purposes. Since the armistice, wave power tools have reached a high state of development and the opinion is generally held that in the mining industry particularly sweeping economies are to be expected by the adoption of this system in place of compressed air.

Briefly the apparatus consists of a wave generator comprising one or two metal cylinders each fitted with a piston driven by any suitable high-speed prime mover and a corresponding wave motor at the far end of the transmission pipe line. The pistons at the wave motor end are suitably connected to the tool or other mechanism to be operated, such as a rock drill, riveting hammer or rotary mechanism, the energy being transmitted through the pipe line in the form of a succession of power waves rendered possible by the slight compressibility of the water or other liquid medium and to a smaller extent by the slight expansion of the pipe line under pressure. The mean pressure in the pipe line for rock drill work is about 750 lb. per sq.in., but the special ball-jointed pipe lines are tested to 15,000 lb. per sq.in. It is claimed that an over-all mechanical efficiency of 50 per cent is attained as against 10 per cent with compressed air, while maintenance costs are one-third and capital costs one-half those obtaining in compressed air work. The usual "frequency" is 2,400 waves or blows per minute and the use of springs and the presence of air at the drill point are eliminated. Lubrication in unnecessary and existing standard appliances can be converted to the new system. The extension of this method of energy transmission is foreshadowed in regard to piledriving, coal cutting, oil conveyors and other industrial applications.

Production of Potash in Alsace—Correction

In our issue of Sept. 1, 1920, p. 382, we published an excerpt from the June 30, 1920, number of the *Frankfurter Zeitung* stating that during 1919 Alsace produced 40,000 metric tons of potash.

H. J. Baker & Bros. of New York inform us that their principals, the Société Commerciale des Potasses d'Alsace, have brought to their attention the fact that this figure is not correct and that the actual figure for potash produced by Alsace mines for the year 1919 was 92,000 metric tons.

We are glad to make the correction accordingly.

Operations in a New Orleans Foundry*

BY FRANK A. STANLEY

THE photographs herewith illustrate some of the operations of a New Orleans foundry engaged in the production of sugar machinery.

The greater part of the work of this firm is of a very heavy character and much of it is loam molding in which the cores and molds are swept up by striking boards or sweeps. The sweeps are made of rigid metal striking bars or spindles held vertically in heavy brackets with suitable bearings and carrying adjustable arms to which the boards are bolted for various sweeping operations. A view of such work is shown in Fig. 1. Most of these molds are made up of brick and loam with a certain amount of clay in spots. The sand or loam inside the brick mold is usually $\frac{3}{4}$ to 1 in. thick, and commonly loam is used as a binder for holding the bricks together. The building up of the mold by the sweeping process is followed by baking over night in big core ovens, the whole brick mold being picked up bodily by overhead cranes and transferred to cars which are run into the ovens.

In molding big rings, drums, cylinders and the like the brick and loam work is built up and swept to any desired height and diameter and both molds and cores are handled advantageously in this manner.

AN INTERESTING MOLDING JOB

A job of special interest is represented by Figs. 2 and 3. This is the molding of a cone-shaped casting which is part of a calandria vacuum pan. The casting is of brass and its diameter is 13 ft. or more, depending upon the size of vacuum pan manufactured. In the conical face of this casting there are cored over four hundred $3\frac{1}{4}$ -in. holes, which are afterward ma-

*Reprinted from *American Machinist*, vol. 53, p. 411; Sept. 2.

FIG. 2. PART OF A MOLD FOR A VACUUM PAN

chined to receive the ends of short copper tubes connecting two of these cone castings together in the assembled vacuum pan in much the same manner as tubes are placed in a boiler. The cone casting in the 12- or 13-ft. size is about 6 ft. high. The thickness of the metal in the wall is about $\frac{1}{2}$ in.

The lower half of the mold, Fig. 2, is built up first,

FIG. 3. OVER 100 CORES IN PLACE

loam and sand being used over a brick center and the cone swept to dimensions ready for baking in the oven. This cone is used as a core or center for the molding of the supper half of the mold, and for this purpose a half-inch thickness of sand is left all the way round on the lower cone to represent the thickness of metal to be run. The top half of the mold is placed in position and molded to the lower cone.

Afterward the half-inch of extra sand thickness is swept off the lower cone and the latter is scribed with a series of lines around its surface for the accurate placing of the $3\frac{1}{4}$ -in. cores to form the openings through the walls. These small cores are dry sand, baked as usual, and are positioned as shown by Fig. 3, where they may be seen in ten circles around the cone.

When the top of the mold is placed in position the metal is poured through the neck and flows down over the sloping cone. About 3,700 lb. of metal is run in this job. The operations illustrated are from the plant of Dibert, Bancroft & Ross, New Orleans, La.

Report on Helium Study Expected Soon

The field work in connection with the helium study being made under the general supervision of the Bureau of Mines will be completed within a month. A report on the work will be available shortly thereafter.

FIG. 1. THE SWEEP IN POSITION

A Disastrous Explosion of Aluminum Dust

A Description of the Investigation by Federal and State Officials of the Causes Leading to the Aluminum Dust Explosion, the Manner in Which the Explosion Occurred and the Results of This Investigation

BY DAVID J. PRICE*

IN RECENT years a large number of disastrous explosions have occurred in industrial plants in both the United States and Canada. Careful investigation of these explosions has shown that in many cases the ignition of flammable dusts created during the operating processes has resulted in large losses of life and extensive property damage. Some of these explosions have taken place in industries where "dust explosions" had not previously been known to occur and the necessity for control methods were not fully recognized. Among the more recent explosions of this nature was an explosion in an aluminum goods manufacturing company's plant in a Northwestern state, which attracted the attention of the engineers engaged in prevention work. The explosion caused the death of six girls and injuries to as many more.

A thorough investigation by Federal and state officials indicated that the explosion was due to the ignition of "aluminum dust" by sparks produced by the friction of a piece of wire on the interior parts of an exhaust fan. This article reviews in a brief manner the circumstances under which the explosion occurred and the results of this investigation.

PROCESSES ENGAGED IN

At the time of the explosion the company was engaged in the manufacture of a complete line of aluminum ware, such as teakettles, teapots, cooking utensils and similar articles manufactured from this material. The aluminum was delivered to the factory in sheet form, varying in size, gage and length, and ranging in width from 7 to 24 in. After the metal sheets entered the factory they were given a light coat-

*Engineer in charge, Grain Dust Explosion Investigations, Bureau of Chemistry, Washington, D. C.

FIG. 1. EXTERIOR VIEW OF PLANT, SHOWING ARRANGEMENT OF BUILDINGS. EXPLOSION OCCURRED ON TOP FLOOR OF WING "C."

ing of grease to assist in the handling and to prevent tearing and cracking during the processes of cutting, punching, stamping and spinning. The grease and dirt were later removed by passing the articles, after shaping, through naphtha, lye or acid baths. They were then dried and ready for the finish application.

Four different finishes were applied, depending on the article. For convenience these finishes may be designated as (1) high polish, (2) satin, (3) acid and (4) emery. The explosion occurred in the satin-finishing department located on the third floor of Wing "C" (Fig. 1).

SATIN-FINISHING DEPARTMENT

The satin-finishing department was located in a room on the third floor approximately 200 ft. long and 40 ft. wide, occupying a little over one-third of the south end. About twenty-five girls were employed in this department. In addition about thirty other persons

FIG. 2. VIEW SHOWING DUST-COLLECTING PIPE, UNDERNEATH WORK BENCH, IN WHICH EXPLOSION OCCURRED

worked in the room in connection with other departments. The girls affected by the explosion worked in the satin-finishing section.

Nine lathes were used in this satin-finish process. These machines were placed on a long wooden bench, and two girls were employed to a machine. The lathes were made up of a spindle approximately 30 in. long with a circular steel brush at each end. This brush was made of fine steel wires, radiating from the center. The satin or "scratch" finish was applied by placing the aluminum ware against the revolving steel brush. During this process fine particles of the aluminum are removed. This creates what might be termed

"aluminum dust," and for sanitary reasons an exhaust system was installed to aid in its removal and improve working conditions for the employees in this room.

DUST-COLLECTING SYSTEM

The steel brushes used in applying the satin finish were surrounded by hoods connected by a 3-in. pipe to a main trunk line, which averaged 12 in. in diameter. It was connected to a 35-in. exhaust fan with a 16-in. opening, which drew the dust from the machine and discharged it to the atmosphere outside. The trunk line extended underneath the bench (Fig. 2) and varied in diameter from 6½ to 16 in. This was about 56 ft. in length and was fitted with four 6-in. hand holes for cleaning purposes. The fan was constructed of steel and had a steel casing. It

deg. below zero; maximum, 16 deg. above zero; relative humidity, 29.7 per cent.

The finishers, all of whom were girls, were seated at their benches, when like a bolt of lightning a blinding flash of fire enveloped them and in an instant their clothing was a mass of flames. Six of the girls died from their injuries, while as many more were seriously burned.

The room in which the explosion occurred was well lighted, having sixteen large windows on the west side and twelve on the east side. Each opening was 6 x 8 ft., thirty panes of glass to the opening.

About one-sixth of these panes were shattered, and a few of the steel window frames were slightly bulged. Both side walls, which were 16 in. thick, were bulged. The west wall was sprung about 3 in. at the ceiling,

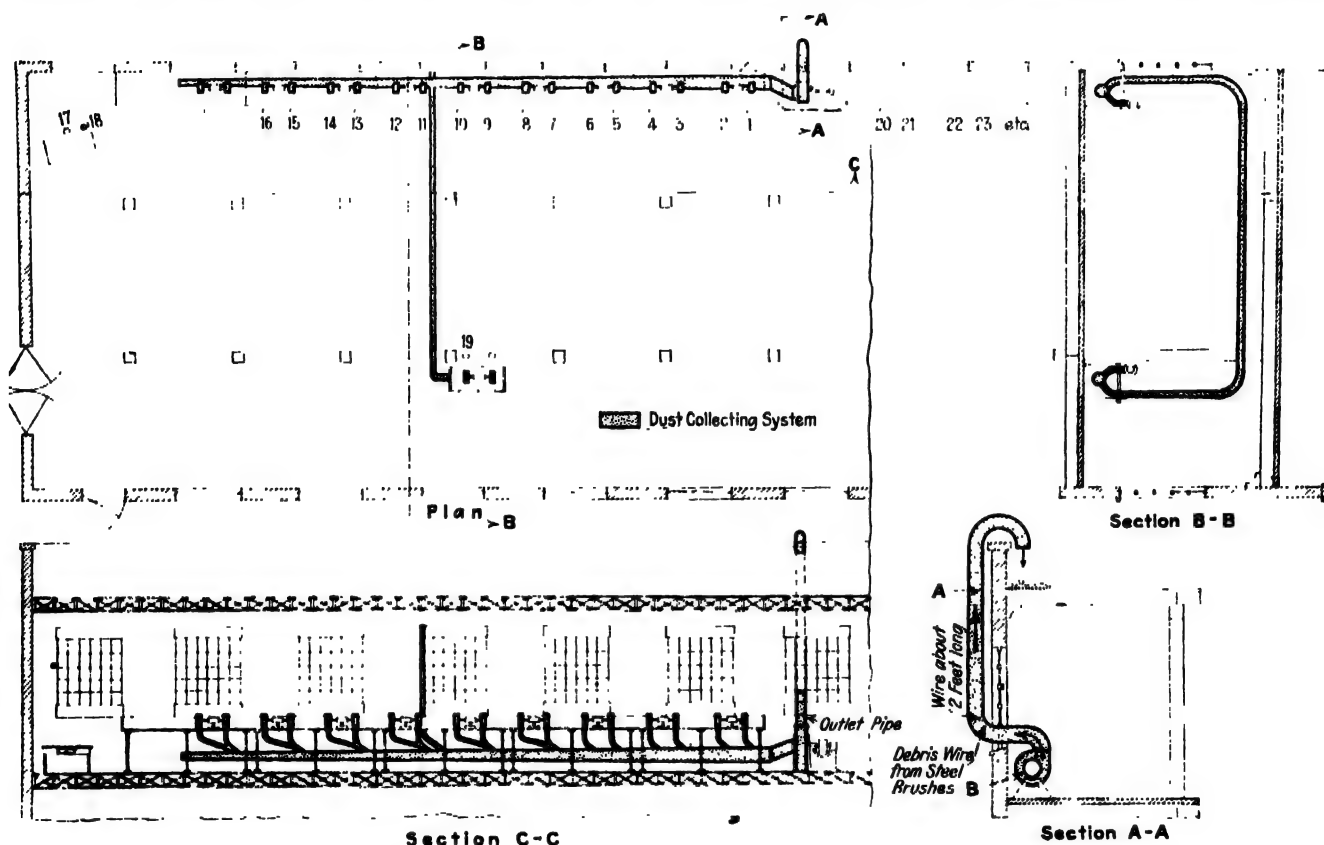

FIG. 3. PLAN, ELEVATION AND SECTION OF OLD SATIN-FINISH DEPARTMENT, SHOWING THE DUST-COLLECTING SYSTEM

ran at 700 r.p.m., and discharged through a 12 x 12-in. opening.

The first three machine hoods were connected separately to the trunk line, while the remaining six machines were connected in pairs, one trunk leading from the main line and then separating one line to each hood (Fig. 3). The girls fatally injured were working at wheels 12, 13, 14, 15 and 16. The other injured employees were located at machines 1, 2, 10, 17, 18 and 19.

ACCOUNT OF EXPLOSION

The explosion occurred about 11 o'clock in the morning, Feb. 26, 1920, while the plant was in full operation with about 800 employees on duty. The explosion was accompanied by a loud report, which was heard for considerable distance from the plant. The weather was clear and cold with minimum temperature for day of 1

and the east wall was forced out about 2 in. at the same point. This crack appeared for a distance of about 50 ft. on each wall.

The damage to the building can be considered very slight, and no surrounding property was affected. The fire following the explosion was readily checked by the efficient sprinkler equipment within the building, combined with the excellent work on the part of the employees and officials, who fought the flames until the arrival of the city fire department. The general condition regarding upkeep and cleanliness of the plant was very good, a factor which must be recognized when the small area affected by the explosion is considered.

CAUSE OF THE EXPLOSION

The cause of the explosion was attributed to a piece of No. 7 B. & S. iron wire about 8 ft. long winding itself around the blades of the exhaust fan. The metal-

he sparks as a result of friction of the wire on the interior parts of the fan ignited the finely divided aluminum dust. The fan was opened by C. W. Keniston, sanitary engineer of the State Industrial Commission, and the wire was found in position in the fan as shown in Fig. 4. A full view of the wire showing its length can be seen in Fig. 5.

How the wire was introduced into the fan was not definitely determined, but the general opinion prevailed that the wire entered the fan from the outside. The exhaust pipe from the fan extended out through a window and up to about 5 ft. above the roof level, and discharged onto the roof.

At the time of the explosion the company was engaged in erecting a new building adjacent, and various kinds of guy wires had been strung to the tops of near-by buildings. Whether through carelessness a piece of wire was laid on the mouth of the exhaust pipe or through malicious intent was placed within the pipe was undetermined at the time of the investigation.

The arrangement of the pipe leading from the fan to the roof was such that the wire coming in from

It appears that the trunk line under the bench was cleaned out at certain periods, approximately every two months. It was the intention to clean out this pipe a few days later. In removing the dust and dirt from the pipe a cable, along with a wooden scraper, was used. The wire found in the fan did not correspond to the description of the cable used in the cleaning process.

FIG. 5. FULL LENGTH OF WIRE FOUND IN THE EXHAUST FAN AFTER THE EXPLOSION

It was estimated that an average of about 30 lb. of dust and dirt was taken from the trunk line every two months.

PREVIOUS EXPLOSION

A slight explosion was observed in this exhaust system a few months previous to the disaster referred to in this article. A workman was engaged in cleaning out the exhaust system of the satin-finishing department prior to the time that the finishers came on for the day's shift. The fan was running, and during the cleaning process the wire being used came in contact with the fan blades. This produced a series of sparks, and an explosion followed which broke open the trunk line at the point it entered the fan. This definitely established the possibility of an ignition of the aluminum dust by sparks produced in this manner.

FLAMMABILITY OF ALUMINUM DUST

Samples of the aluminum dust were collected from the pipes of the suction system. In sifting the dust through cheesecloth of ordinary mesh onto the flame of a match, the dust readily ignited with brilliancy

FIG. 4. VIEW SHOWING POSITION IN WHICH A PIECE OF NO. 7 B. & S. IRON WIRE WAS FOUND IN THE EXHAUST FAN

the outside would be required to pass through two 15-deg. turns. It is, therefore, possible that the wire may have been lodged in the pipe for some length of time, gradually working down by the vibration of the pipe until eventually it was struck by the paddles of the fan.

It was stated that two girls within 10 ft. of the fan, employed at a wrapping bench immediately north of the exhaust fan, heard a noise within the fan a short time prior to the explosion. This noise was heard distinctly on two occasions previous to the blast. It appeared to be simply a rattle, and one girl on hearing it arose from her chair and walked away from the fan. The explosion occurred before she could reach her sister, a distance of probably 8 ft. The second girl, who was sitting closer to the machine, heard the rattle three times and stated that the explosion occurred immediately following the third noise and that she saw smoke first before the blinding flash occurred.

Two pieces of wire were removed, one from the fan and the other from the exhaust pipe. This indicated that probably the original piece of wire was broken; one piece winding itself about the blades, and the other sticking in the pipe.

FIG. 6. VIEW SHOWING BRUSHES USED IN THE SATIN-FINISHING PROCESS AND CONNECTIONS LEADING INTO THE MAIN TRUNK LINE. NOTE THE COVER HOOD ON THE BENCH

and rapid propagation of flame. The Bureau of Mines, U. S. Department of the Interior, reports that "aluminum dust burns quietly when in a pile, but if this pile be disturbed in such a manner as to raise a cloud of dust into the air the burning takes place with explosive violence. If a dust cloud already formed that has a density within the explosive limits be ignited a violent explosion results." In experiments conducted in that bureau it was found that in some cases aluminum dust could be ignited at temperatures even lower than those necessary for the ignition of 200-mesh standard Pittsburgh coal dust. At 800 deg. C. the aluminum dust cloud ignited with a brilliant flash, while higher temperatures were necessary to ignite coal dust.'

RELATION OF DUST-COLLECTING SYSTEMS TO EXPLOSION FREQUENCY

A number of disastrous dust explosions originating in the dust-collecting systems have occurred in manufacturing plants in recent years. In an explosion of

PROPOSED NEW SYSTEM

The proposed new system, plans of which are shown in Fig. 7, is based on the fact that the aluminum and iron dusts, when in a finely divided state and mixed with air in proper proportions, form an explosive mixture, which can be ignited by an external source of heat or flame. The system was designed under the direction of C. W. Keniston, engineer in charge of industrial hygiene of the Industrial Commission of Wisconsin, and the following description is taken from his report to the commission:

1. The new system proposes to furnish a positive inlet for all air exhausted from the building, this to be provided for by an efficient ventilation system.
2. No exhaust ducts to be used. (Induced or secondary currents of air required.)
3. No exhauster used or no machine (through which air currents containing explosive mixtures are carried) in which moving parts are made of materials which could generate sparks.

FIG. 7. PLAN, ELEVATION AND SECTIONS OF NEW SATIN-FINISHING DEPARTMENT, SHOWING THE PRIMARY AND SECONDARY AIR DUCTS

chocolate dust in an Eastern plant, the explosion originated within the exhaust fan, presumably from sparks struck by foreign materials. The entire plant was destroyed, three lives were lost and the total property loss was estimated at \$1,000,000. An explosion of flour dust occurred in a Western mill a few months ago in the trunking leading from the grinding rolls to the exhaust fan. Under the method of installation in these systems, as a rule, the dust and air are so well diffused in the pipes leading to the fan as to permit an explosive mixture to be present. When an ignition source of sufficient temperature is introduced, the dust cloud is readily ignited and the explosion propagates. The relation of dust-collecting systems of this nature to dust explosions and fire frequency has made evident the necessity for research engineering investigations to develop effective methods of prevention.

¹Technical Paper 152, "The Inflammability of Aluminum Dust," by Alan Leighton, Bureau of Mines.

4. By the elimination of exhauster and exhaust ducts this system eliminates the contributing conditions to the explosion hazards and also the opportunity for the direct cause of the explosion to ever occur.

Tests and research work demonstrating the feasibility and practicability of the proposed system were made. The ducts for primary and secondary air are shown in Fig. 7. It will be noted that these secondary air currents, which pick up and carry out the aluminum dusts, pass through no equipment which could be an explosion chamber. Further details can be obtained through the Industrial Commission.

A certificate of inspection was issued to the company reading as follows:

There are required in your places of employment ventilation systems so designed, constructed and operated that the conditions of employment can be considered safe for health by the Industrial Commission.

Plans and specifications are to be submitted within a reasonable period of time. These plans must show the items on the following list which govern the design of your systems:

PLANS AND SPECIFICATIONS FOR VENTILATING AND EXHAUST SYSTEMS

List of factors which govern the design, and those details which govern the proposed installations should appear on the plans:

- General surroundings.
- Plans and elevations—with section if necessary.
- Location of windows, roofs, partitions, exits.
- Location of equipment and character of the work performed.
- Number of persons employed and their distribution.
- Available cubic feet of air space (total space less that taken up by equipment and materials).
- Location of proposed ventilation and exhaust machinery.
- Location and sizes of air inlets and outlets.
- Location, size and shape of ducts and pipes.
- Location, size and type of fans and motive power or ventilator.
- Materials used in construction of fans and ducts.
- Cubic feet of air moved per hour.
- Velocity of air per minute produced at the throat of the hoods of exhaust systems.
- Any proposed heating, cooling or purification apparatus used in connection with the system.
- Any apparatus used to take care of the discharge of the system.

After the above-mentioned research had been carried on to the satisfaction of the Industrial Commission, the following recommendations and requirements were added to the above-mentioned certificate of inspection:

The following recommendation applies to the new plant, fourth floor. We recommend that the system required as a protection to health in the satin-finishing department be designed, constructed and operated in the following-described way so that the conditions of employment can be considered safe for health in all ways, including explosion hazards:

Static suction required in the hoods must be produced as an induced current of air by the use of a pressure air jet. This can be constructed in accordance with the experimental data found to be practical in a series of experiments conducted especially for this particular problem. The air currents carrying the dust must be carried to the outside atmosphere through the shortest pipe possible and without passing through any fans or large conveying ducts similar to those used in other exhaust systems. The air jets must be so constructed that the operator of each wheel may control the air jet used for its suction.

IMPORTANCE OF DUST EXPLOSION PREVENTION TO INDUSTRIES

The extensive losses to life and property as a result of the large number of dust explosions occurring in manufacturing establishments fully emphasizes the need for a thorough engineering study of the problem. Large quantities of foodstuffs are destroyed in these explosions and fires in the industries where food products are manufactured. In a period of less than 12 months—May, 1919, to April, 1920—at least six disastrous explosions, causing a loss of eighty lives and property damage to the extent of \$7,000,000 have occurred. In addition a large number of explosions have taken place in factories, without any life loss or extensive damage.

In a "starch dust" explosion in a factory in the Middle West during the past year forty-three lives were lost and \$3,000,000 property damage was done. In two explosions of grain dust, in modern elevators constructed of fire-resistive materials, one in the United States and the other in Canada, twenty-four lives were lost and as many others injured, with both plants badly damaged. In fighting a fire in a spice plant a few months ago, eighteen firemen were caught when a wall was "blown out" during the progress of the fire. Four of the firemen lost their lives and a thorough investigation suggested the possibility of the falling timbers

forcing a cloud of "spice dust" onto the flames of the fire, causing an explosion.* Explosions are occurring in sugar refineries, starch factories, flour mills, grain elevators, chocolate plants and other similar industries where flammable dusts are created.

ENGINEERING INVESTIGATIONAL WORK

The Bureau of Chemistry of the U. S. Department of Agriculture, in co-operation with the milling and grain companies throughout the country, is conducting investigational research work to develop methods for the control and prevention of dust explosions in industries where grain or its products are handled. In order to assist the bureau in this work and to obtain all information available pertaining to the behavior of these explosions, the disaster in the aluminum plant was carefully studied by the engineers. This procedure has also been followed in the investigation of dust explosions in other types of industrial plants.

The results of the investigation after the explosions in not only the grain-handling plants but in the other manufacturing establishments as well have developed many essential lines of engineering work. The explosions are not only occurring in many cases in industries where they had not been experienced previously but the investigations are developing new causes relating closely to construction of plant, mechanical operating equipment, dust-collecting and control methods and similar factors. The explosions have taken place in some of the largest manufacturing plants in the United States and Canada, where the safety engineers were applying all known preventive measures. Before dust explosions of this nature can be effectively controlled, these new problems arising must be solved, in order to reduce our losses to life, food and property.

A Method for Determining the Opacity of Eye-Protective Glasses to Ultra-Violet Rays

A quick method for determining the opacity of eye-protective glasses to ultra-violet rays has been worked out by the U. S. Bureau of Standards. The photographic method usually employed requires several hours for making such a test, while by the new method, which is radiometric, a test can be made in a few minutes. The test is based upon the fact that all glasses are opaque to radiations of wave lengths less than 0.3 micron (1 micron = 1/1,000 mm.). It is, therefore, only necessary to examine eye-protective glasses for opacity to ultra-violet radiations of wave lengths 0.3 to 0.4 micron. Radiations of these wave lengths are easily obtained without employing a spectroscope by simply filtering the light from a quartz vapor lamp through a suitable glass screen placed over a vacuum thermopile. Measurements of one part in 10,000 are easily obtainable, whereas on the basis of the requirements of the proposed Safety Code for Head and Eye Protection, an accuracy of one part in 1,000 is all that is necessary.

Rice Straw as Raw Material in the Paper Industry

According to *Eastern Engineering*, a combine of Dutch paper manufacturers proposes to establish a factory in the Dutch East Indies for the manufacture of paper from rice straw. It is stated that excellent writing paper has already been made from this material.

Legal Notes

BY WELLINGTON GUSTIN

Oral Agreements Excluded When Written Contract Is Neither Uncertain Nor Ambiguous

Judgment for the Detroit Copper & Brass Rolling Mills has been affirmed by the United States Circuit Court of Appeals, Eighth Circuit, in the action brought against it by the Century Electric Co., of St. Louis. The controversy arose out of a written contract of sale of 400,000 lb. of brass rods, a portion of which were returned by the Century company because it was claimed they were too hard to be cut and made into brass primers by automatic screw machines.

The Detroit company defended on the ground that it was under no obligation to make the rods of such a degree of hardness that they could be so machined. The written agreement contained no covenant of that nature.

The Century company offered to prove that in the negotiations for the contract, just before it was made, the Detroit company made an oral agreement to that effect. The court ruled out this evidence because it varied a written contract, by adding a new covenant to it. The Century company contended that there was an implied warranty to that effect, but the trial court held otherwise, and directed a verdict for the Detroit company. An appeal was had on these disputed grounds.

In the written contract the ingredients of the brass rods are stated in these words: "The basis for the mixture to consist of 60 parts copper and 40 parts spelter." Other provisions of this contract covered the amount of the rods, times, place and manner of delivery, prices and payments. The contract ends with the statement that the written agreement is the final understanding of the parties and no changes may be made unless reduced to writing and signed by both parties.

This sale was solicited by the Century company, the purchaser, which had a contract with the Bethlehem Steel Co. to furnish Russian brass primers for 3-in. shells. The Century company asked for quotations on the brass rods described in the contract, and the Detroit company gave prices, followed by a personal interview of four hours between the agents of the corporations and the execution of the contract upon the close of that conference.

WRITTEN CONTRACT CONCLUSIVE, DECIDES COURT

The Century company offered to sustain its claim that the Rolling Mills made an oral agreement and an implied contract to sell it brass rods soft enough to be readily cut and made into brass primers by the use of automatic screw machines. In its opinion the Court of Appeals pointed out that the written contract clearly describes the ingredients of the mixture. When the parties were negotiating for the contract, the buyer might have required, and if the seller had consented, might have obtained a provision in the written agreement that the seller would sell and deliver brass that could be readily cut and made into Russian primers by the use of automatic screw machines, but it did not do so, said the court. When the parties selected, out of the numerous suggestions discussed during their four-hour conference, the terms to which they agreed and which

they embodied in their written contract, the legal presumption arose that they had rejected and did not agree to or intend to agree to the suggestions discussed in the negotiations which were omitted from the writing. And where, as in this case, the written contract imports a complete legal obligation free from uncertainty and ambiguity, that presumption is conclusive, said the court.

It further said the rule that all previous negotiations are merged in the written agreement, and that parol evidence to modify it is incompetent, rests upon the conclusive presumption that the parties have written into it every material term and item of their agreement, and evidence of a contemporaneous parol contract is as incompetent to add another covenant or term to the writing as it is to change a covenant or to withdraw it therefrom.

However, the buyer contended that the seller knew the custom of cutting and making the rods into Russian primers by the use of automatic screw machines, that the seller represented that he could produce the goods to make such primers, that it had sold brass rods for this purpose to another concern, which had bought brass rods from another brass company, which were defective, and had finally come to it to get the proper kind of brass, and therefore there arose an implied warranty that the brass it sold the Century company would be of such proper hardness.

ALL AGREEMENTS SHOULD BE IN THE CONTRACT

Answering this contention, the court said that if the buyer had employed the seller to make and deliver brass rods to be cut and made into Russian primers by automatic screw machines, and had intrusted to the judgment and skill of the seller the ingredients and composition of the mixture from which the rods should be made and the percentage of lead which the rods should contain, such a warranty might have arisen.

It might have specified and written into the contract the exact proportion of lead the bars should contain, so that they could be readily machined, for the proportion of lead in the rods conditioned their hardness. It might have written into that contract that the seller should use such a proportion of lead as would make them readily machinable. It did neither of these things, but expressly provided in the writing that the mixture should contain 40 parts spelter and 60 parts copper, and then, three days after the making of the contract, telegraphed the seller that the rods must contain only 1 per cent of lead, which latter terms were accepted by the maker.

Therefore, the seller made and delivered a product which complied with all these requirements of the contract and the rule applies that, when a known, described and definite product is ordered of a manufacturer, although it be stated by the purchaser to be required for a particular use, yet if the known, described and definite thing be actually supplied, there is no implied warranty that it shall answer the particular purpose intended by the buyer (cf. 79 Fed., 43 and 611).

Again, the terms of the written contract show that the express warranty of the contents of the mixture and of the proportion of the lead in it, which conditioned the degree of its hardness, raises the conclusive presumption that no other warranty of their degree of hardness was implied. The express warranty of one or more of the qualities of an article excludes an implied warranty of the same qualities or of other qualities of a similar nature.

Steel Rails From Sink-Head and Ordinary Rail Ingots—I

General Plan of Investigation—Ingot Practice—Temperature Observation—General Comparison of Two Ingot Types—Comparison of Chemical Composition—Items Relating to Manufacture

BY GEORGE K. BURGESS*

THE results of the experimental rolling into rails of several types of ingot, including several designs of sink-head ingot and others, with the co-operation of the Maryland Steel Co., reported by Messrs. Hadfield and Burgess¹, looked sufficiently promising to the rail committee of the Pennsylvania Railroad to warrant the purchase of 100 tons of ingots cast by Sir Robert Hadfield in England, in order to make a more effective study of the suitability of this type of sink-head ingot for the manufacture of rails. It was also considered desirable to carry out similar series of tests of ingots of ordinary rail steel rolled at the same time and under as nearly identical conditions as possible in the same mill. President F. W. Wood of the Maryland Steel Co., Sparrows Point, Md., offered the facilities of that plant for this investigation, as in the case of previous experiments reported by Hadfield and Burgess. The rolling of ingots for the present investigation was done in 1915 at the Sparrows Point plant, then known as the Maryland Steel Co., now a part of the Bethlehem Steel Co.

The planning of the details of the investigation, after correspondence with Sir Robert Hadfield, was made by A. W. Gibbs, chief mechanical engineer of Pennsylvania Railroad Co.; F. W. Wood, president of Maryland Steel Co., and the present writer, and the tests were carried out by members of the technical staffs of their representative organizations, to whom acknowledgment is here made for their indispensable aid.

It was expected by Sir Robert Hadfield that the sink-head ingots made under this system² would yield rails of remarkably high quality as regards "soundness, freedom from all piping and all segregation." From an inspection of the data concerning the manufacture of the ingots made by this process he also felt confident

in stating: "This shows in a remarkable manner the uniformity of the ingots, also that every one of them is perfectly sound, free from blowholes, with no piping and segregation below 8 per cent discard."

The results of the present investigation of thirty-seven ingots of the Hadfield type (Fig. 1) show that he was not far astray in the confident prediction of uniformity, physical soundness, and freedom from chemical segregation. In fact, it is difficult to imagine thirty-seven ingots from as many different heats of bessemer steel more uniform in quality and properties and as free from those undesirable qualities and uncertainties that beset the ordinary ingot.

The ingots with which they were compared, the prod-

FIG. 1. ONE HUNDRED TONS OF HADFIELD INGOTS SUPPLIED TO THE PENNSYLVANIA RAILWAY.

uct of three heats, five from each heat, or fifteen ingots in all, are not less instructive, in that each group, or heat, represents a distinct practice in open-hearth manufacture. In this investigation, therefore, from the point of view of steel-making, we are really comparing the products rolled from two types of ingot representing four methods of manufacture.

The rolling, inspection, tests and analyses were car-

²See also the valuable paper comparing American-made sink-head and ordinary ingots for rails by Edward F. Kenney: "The Commercial Production of Sound and Homogeneous Steel," *Am. Iron and Steel Inst.*, p. 144, 1915.

³The method in brief consists in casting the ingots on cars, usually with the small end down. Each ingot mold is provided

with a sand top. After the mold is filled to the desired height with steel, a layer of slag about 4 in. thick is placed upon it and the remainder of the mold is then filled with charcoal. Then, through suitable piping, an air blast is directed in numerous jets upon the charcoal (for 20 to 40 min.), which is burned thereby, the combustion supplying additional heat to the top of the ingot, which helps to keep the top fluid and to retard its solidification, while the lower parts are rapidly losing heat by its transfer to the mold. Sir Robert A. Hadfield, "Plant for Hadfield Method of Producing Sound Steel Ingots," *Trans., A.I.M.E.*, 1913, p. 669.

ried out with the greatest care, and by a series of actual weighings all the material from the several ingots was accounted for.

INGOT PRACTICE

Since the sink-head ingots were cast in England and rolled in this country, they were necessarily subjected to the unusual process, at least in rail manufacture as ordinarily practiced, of reheating from the cold condition. The plan was considered of allowing at least some of the comparison ingots to go "stone cold" and reheat them before rolling. However, in view of the fact that the ordinary type of ingot is not designed to meet this condition, which practically never obtains in practice and which therefore would be a possible misleading condition to impose on the comparison ingots and of no practical value, the Maryland ingots were all rolled directly after being cast. These ingots were stripped from 20 to 30 min. after casting and put while still hot into the soaking pits, where they remained from 1 hr. 40 min. to 2 hr. 23 min.

The sink-head ingots after preliminary heating were charged into relatively cool pits. The heat was gradually turned on after $\frac{1}{2}$ hr. and the ingots remained in the pits from 17 $\frac{1}{2}$ hr. to 21 $\frac{1}{2}$ hr. The thirty-five sink-head ingots which were rolled were divided into three series and rolled on successive days, Aug. 16, 17 and 18, 1915. Three heats of comparison ingots were rolled, one on Aug. 16 and two on Aug. 18. There was no delay or other unusual condition in the mill during the rolling. The ingots of a group were rolled in succession, without intermission, and after the mill had been warmed up by rolling at least one complete heat of the regular product of the mill.

TEMPERATURE OBSERVATIONS

Temperature observations were taken of the soaking pits before, and at intervals after, immersion of ingots

of both types; of all ingots in the blooming mill; and of rails from both series of ingots at the finishing pass. In order to heat them gradually, the Hadfield ingots lay on the surface of the soaking pits approximately 12 hr. before charging. They were too hot to bear the hand comfortably when charged, at which time their estimated temperature was about 50 deg. C. (122 deg. F.). The pits which received these sink-head ingots were allowed to cool to the temperature of 600 deg. C. (1,112 deg. F.) to 750 deg. C. (1,382 deg. F.). (Table I.) The immersion of the ingots further cooled the pits by about 200 deg. C. (392 deg. F.) as measured immediately after charging. The gas was turned on the pits $\frac{1}{2}$ hr. after charging. The Maryland ingots were charged into the soaking pits hot according to the usual practice.

The temperatures of Table I were taken with a platinum-rhodium thermocouple connected to a pivot type of indicator. The couple was enclosed in nickel sheath except the tip, which was exposed. In some cases the temperatures were obtained by the use of an optical pyrometer of the Morse type.

By means of the optical pyrometer, temperatures of the ingots were taken during rolling. Average values, obtained from seven or eight observations with optical pyrometer at alternate passes, after the first roughing pass, were taken of the ingots in the blooming mill. The temperature of the steel at the surface was lowered about 17 deg. C. (63 deg. F.) to 40 deg. C. (104 deg. F.) during the rolling into blooms. Typical illustrations of rolling temperatures are given in Table II for several ingots of both types. Table I contains finishing temperatures of Hadfield rail bars, taken at the finishing pass, by sighting on the center of base of rail bar with an optical pyrometer. Each observation is the average of two readings.

In Table III are similar data for the comparison ingots and rails, except that the pit temperatures were not taken. It will be noted that good uniformity of rolling and finishing temperatures was obtained.

A series of measurements was taken to compare the temperatures of this investigation taken at the finishing pass with those taken at the hot saw by sighting on the head of the rail. The reading noted in Tables I and III of finishing temperatures should be reduced by about 11 deg. C. (52 deg. F.) to correspond to previous observations at hot saw.

The observed ingot and rail temperatures were taken on the outside oxidized surfaces, which are colder than the interior metal by 75 deg. C. (167 deg. F.) to 100 deg. C. (212 deg. F.). This would account for the apparent discrepancy between the soaking-pit and ingot temperatures, and would make the average true finishing temperature somewhat higher than 1,100 deg. C. (2,012 deg. F.).

GENERAL COMPARISON OF THE TWO INGOT TYPES

Method of Numbering Ingots. The sink-head ingots were numbered H1, H2, etc. . . . H37, and the ingots made in the ordinary manner were numbered M1, M2, etc. . . . M15.

Weight of Ingots. The sink-head ingots were weighed cold and the others were weighed hot. The approximate weight of the sink-head ingots was 5,300 lb. each, and of the Maryland ingots 7,800 lb.

Size and Shape of Ingots. The English-made ingots were cast with sink-head on large end, while the American-made ingots were cast small end up. Hadfield's ingots were 19½ in. square on top, 17½ in. square at the bottom and 50½ in. high, exclusive of 13½ in., the approximate height of the sink head. American ingots were 18½ in. square on top, 19½ in. square on bottom and

¹Bureau of Standards Tech. Paper 38, "Observations on Finishing Temperatures and Properties of Rails."

63 in. high. Further details of the sink-head cavities may be had from Table IV.

Loss in Heating. The sink-head ingots were weighed while cold before reheating and the comparison ingots were weighed while hot. The abnormal loss in weight sustained by the former should be deducted from the nominal ingot weight in computing the net ingot. It so happens that the average bottom bloom crop for the ingot made in an ordinary manner is 0.5 per cent greater than for the sink-head ingot; so that if the loss on heating for the comparison ingots is taken as 0.5 per cent there will be an exact balance. The English cast ingots remained in the soaking pits about ten times as long as the comparison ingots. If it is, nevertheless, preferred to compare actual percentages of material available for rails, that from the sink-head ingots should be increased by 2.5 per cent, since there was a loss of 3 per cent, of which about 2.5 per cent can be charged to reheating. When this correction is made, it will later be shown that the average sink-head ingot gives about 84.8 per cent material available for rails instead of 81.9 per cent. (Ingot H24 should not be used in the computation, as it was accidentally given an excessive bloom crop.) The expression "material available for rails" as here used refers to physically sound steel only. Subsequent chemical analyses showed a much greater discard was necessary to eliminate segregation above 12 per cent, as will be shown later in Tables XII and XIII.

Comparison by Heats. It will be noted that the three heats of comparison ingots have each very distinct characteristics, as expressed, for example, in material available for rails, which are the results of varying open-hearth and casting practice. In group M1 to M5, the percentage of material available for rails was 86.9 per cent; in group M6 to M9 85 per cent, and in group M11 to M15, 65.8 per cent (Table VI). It was for this reason that, in addition to the general average of prop-

TABLE IV. CHEMICAL COMPOSITION AND HEAD PARTICULARS OF SINK-HEAD INGOTS, REPORTED BY SIR ROBERT HADFIELD

erties of all Maryland rails, averages were computed for each of the three Maryland heats. The three rollings of the Hadfield ingots show great uniformity, however expressed, and this indicates that the manufacture of the ingots in all cases apparently was carried out in accordance with a uniform practice.

Inspection of Ingots. The sink-head ingots were examined while cold for surface defects, and the surface condition of all ingots was noted by another observer as they passed through the blooming mill. There were side splashes, rough sides and rough corners on nearly all the sink-head ingots, and only four of the thirty-five were noted as clean blooms in rolling, as compared with eight clean blooms from the fifteen comparison ingots.

COMPARISON OF CHEMICAL COMPOSITION

Sink-Head Ingots. The chemical composition of the sink-head ingots (Table IV) and the rails therefrom shows a remarkable degree of uniformity. Thus, for the

per cent, with a deviation of 0.004. For the top of the web the concordance is somewhat less good. Manganese and silicon are very uniformly distributed.

Comparison Ingots. These ingots were cast with small end uppermost of analysis shown in Table V and

TABLE V. COMPOSITION OF MARYLAND STEEL

Heat No.	2x4497	1x3632	2x4510
Ingots Nos.	M1 to M5, incl.	M6 to M10, incl.	M11 to M15, incl.
Per cent carbon	0.608 to 0.630	0.642 to 0.654	0.642 to 0.650
Per cent silicon	0.148	0.185	0.191
Per cent sulphur	0.067	0.092	0.097
Per cent phosphorus	0.010	0.014	0.019
Per cent manganese	0.710 to 0.720	0.650 to 0.660	0.760 to 0.810
Per cent chromium	0.270	0.290	0.270
Per cent nickel	0.760	0.780	0.760

except for a nickel content of 0.75 per cent and chromium content of 0.28 per cent accompanying the Cuban ore used in the blast furnace, they were of a composition and uniformity comparable with the sink-head type, the average "O" (tread) position having a car-

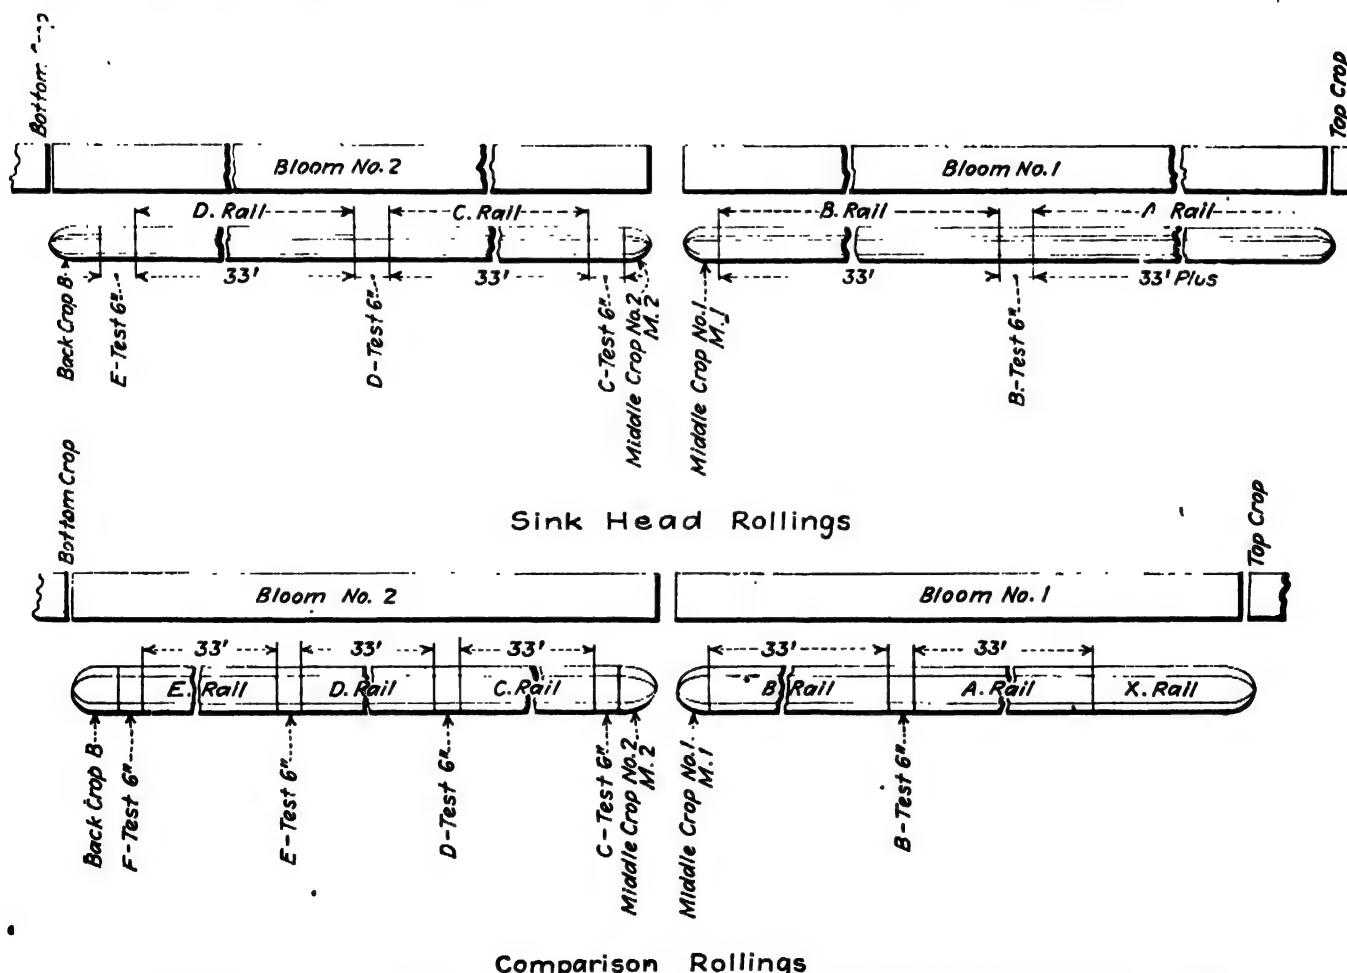

FIG. 2. DIAGRAM SHOWING CUTTING OF BLOOMS AND RAILS FROM INGOTS OF BOTH TYPES

"O" analysis (near the tread) the average carbon is 0.648 per cent, with an average deviation from mean of 0.017. If we take the "C" test piece (top crop from the second bloom) as representing the ingot composition, the average for carbon at the top of the web is 0.644 per cent and near the tread is 0.653 per cent, the average deviation from mean in each case being 0.017.

The average phosphorus content of the tread position is 0.032 per cent, with an average deviation of 0.002; for sulphur (same position) the average is 0.047

bon content of 0.645 per cent (sink-head 0.648 per cent), with an average deviation from mean of 0.036. The manganese content is 0.70 per cent, as compared with 0.89 per cent for the sink-head ingots, phosphorus 0.019 per cent (sink-head 0.047 per cent). Group M11 to M15 has an average phosphorus content of 0.028 per cent, which quite closely agrees with that of English-cast ingots. This sub-group is also from its method of manufacture the best to compare with the imported ingots.

The sulphur content of the comparison ingots fol-

lows the grouping by heats; the tread analysis of the C rail, for example, for ingots M1 to M5, has a sulphur content of 0.076 per cent; for ingots M6 to M10, the sulphur is 0.101 per cent; for ingots M11 to M15, the sulphur is 0.118 per cent. The manganese and silicon of the first two groups are practically identical, while both are slightly higher in the third group (M11 to M15). Chromium and nickel are practically constant at 0.28 per cent for the former and 0.75 per cent for the latter for all three groups.

DISPOSITION OF INGOTS

Of the thirty-seven sink-head ingots cast at Sheffield, thirty-five were rolled into blooms at the Sparrows Point mill and the remaining two ingots were sectioned longitudinally for metallographic examination. The examination of H32 was made by the Bureau of Standards and H37 by Hadfields, Ltd. In addition to splitting two ingots, it was also decided to examine similarly top blooms from one of each of the two types of ingot (H5 and M10). The blooms and ingots examined in this manner were selected at random. All blooms were rolled into rails directly without reheating and all material was accounted for by actual weighing.

BLOOMING MILL

All ingots were rolled in thirteen passes in a two-high mill to blooms 8 x 8½ in. The English-made ingots entered the blooming mill with the sink-head toward the rolls, one-half receiving the first or "squaring up" pass in this direction, no draft being given on second pass, while the other half were given no draft on the first pass, the "squaring up" being done on pass No. 2. The Maryland ingots were rolled according to ordinary practice entering the rolls the small end first.

BLOOMS

Each ingot was cut into two blooms (8 x 8½ in.) as shown in Fig. 2, and rolled directly into rails—that is, without reheating of blooms. The second bloom from sink-head ingots made two rails (C and D), and that from Maryland ingots three rails (C, D and E). The first bloom from the sink-head type of ingot made a B and (generally) a short A rail; the first bloom from the comparison type of ingot made a B, A and (short) x rail. The blooms were sheared top and bottom as little as possible for the safe passage of the bar through the rolls. Each piece cut was marked, weighed and preserved.

RAILS

In the rail mill there are six passes in the roughing rolls, four in the intermediate rolls and one finishing pass, making a total of twenty-four passes from ingot to finished rail. The rails, which were Pennsylvania 100-lb. section, were cut at the hot saw as shown in Fig. 2.

The rails were inspected for surface defects, piping and discard to physically sound steel. The classification into "firsts" and "seconds" from surface conditions was made by the Pennsylvania Railroad Co. inspectors; the discard to "physically sound steel" was made by cutting back in 5-ft. lengths.

There were a relatively large number of "second" rails from the sink-head ingots, sixty-one out of a total 104 rails, or 59 per cent. There were only four in fifty-seven from the comparison ingots, or 7 per cent. The A rails are not included for either group.

There appears to be no reason why ingots of the sink-head type should not be as well surfaced as any other, and the high percentage of seconds should not be attributed to the type of ingot, as the bottom of the sink-head was well within the "A" rail, which was not classified. Probably the severe and unusual reheating conditions contributed somewhat together with the original surface condition as influenced by condition of the molds and teeming practice, toward producing the large number of "seconds" from the Hadfield ingots. A large percentage of "seconds" was similarly obtained from the reheated Hadfield ingots reported on by Hadfield and Burgess'.

(Parts II and III will be published later.)

Free Thiocyanogen

BY CLARENCE JAY WEST

In 1815 Gay-Lussac discovered that cyanogen, C_2N_2 , could be prepared and that it was capable of existing in the free state. This was the first organic "compound radical" discovered. Cyanogen was called a radical by Liebig because

1. It is a never varying constituent in a series of compounds.
2. It can be replaced in these compounds by other simple bodies.
3. In its compounds with a simple body this latter may be easily separated or replaced by equivalent quantities of other simple bodies.

Of these three chief and characteristic conditions of a compound radical at least two must be fulfilled if the substance is to be regarded as a true compound radical.

Other compound radicals which are well known are nitrogen peroxide, NO_2 , sulphur dioxide, SO_2 , etc.

Following the discovery of cyanogen, Liebig in 1829 undertook to prepare free thiocyanogen by the action of chlorine upon silver, lead and potassium thiocyanates under various conditions, but was unsuccessful. The next step came when Linnemann (1861) shook an ether solution of iodine with silver thiocyanate. Silver iodide was formed, but the substance in solution decomposed so easily that it was not studied.

That free thiocyanogen was really present in this ether solution has been shown by the recent work of Söderbäck [*Ann.*, vol. 419, p. 217 (1919)]. He has shown that chlorine, bromine or iodine acting on a number of metallic thiocyanates such as silver, lead, mercuric, cadmium, zinc and cuprous, in a variety of solvents such as ethyl chloride, ethyl bromide, carbon disulphide, carbon tetrachloride, benzene, absolute ether, etc., yields a precipitate of the metal halide and a solution containing free thiocyanogen. The substance is best isolated from about a twice normal solution in carbon disulphide, by cooling with ether and liquid CO_2 , and by filtering in a funnel cooled in the same way. Thiocyanogen forms rhombic plates, white to pale yellow in color, which melt at -2 to -3 deg., to a pale yellow liquid. These may be supercooled to -20 deg., but at -30 deg. always solidify. The liquid is unstable and quickly decomposes, changing from yellow to a dark reddish brown. While the crystals are soluble in organic solvents, water decomposes them, yielding thiocyanic acid, $HCNS$, hydrocyanic acid, HCN , and sulphuric acid. Söderbäck believes the molecular formula to be $(SCN)_2$, from its reaction with hydrochloric acid.

Education of the Engineer

In Fifty Years Engineering Has Become a Learned Profession, a Wonderful Advance Considering the Conservatism and Complacency of Educators and Public—Yet No Better Engineers Are Being Produced, Largely Because of Inattention to Fundamentals

BY ROBERT S. WOODWARD*

WHEN I left the University of Michigan forty-eight years ago I found, much to my surprise and chagrin, that people whom I took to be the best educated people of the time led me to believe that there was no prospect that a man who has this elementary training we call engineering could become either a scholar or a gentleman. The nearly universal opinion was that the only way to achieve those desirable ends was to pursue a course of study which led to the degree of A.B. It was thought that the pursuit of studies in mathematics, say, beyond the confines of Euclidean geometry, would be narrowing in their influences, and that prejudice, I am sorry to say, has persisted in some quarters even to this day.

ENGINEERING: NOW A LEARNED PROFESSION

Few of you young men who are here can realize the great change that has taken place since then. The engineer has now come to be recognized as a member of a learned profession. In those old days there were only three learned professions recognized—those of law, medicine and theology. The great class of people whom we then called humanists, and whom we still call humanists, were separate and apart from the professional classes, and they, in those days as in these, held themselves to be far above the groveling crowd, even in professional matters. But in the meantime great progress has been made, and I think perhaps you may be interested to know what, in a brief statement, is my verdict as to the reason why you have achieved so much. To put it in a homely way, such as was used in New York City when I dealt somewhat in Tammany politics, the chief reason for your success is that you have been willing to "say little and saw wood." In other words, you have been willing to have your measure taken by merit alone, and that, in the long run, is the only ground on which a man may be expected to stand with any degree of permanence.

The title of my address, assigned to me, by the way, is "Education of the Engineer." But I fear that some of you don't know that in respect to education I am both a Philistine and an iconoclast. I have been at war with education all my life. I think in the courts it would have been said, if my testimony had been solicited, that I was a recalcitrant witness. I am disposed to think, although I have been connected with three universities, including the University of Michigan, and have been not lacking in experience as professor and as administrator in educational affairs, that the general verdict would be that I am far from orthodox; so that if I vent some of my spleen, you should not be surprised.

However, I am disposed to think that agitation is a

good thing, and one of the things we must have; after the fashion of the Irish politician in Philadelphia, I have come to think, as he put it, "It is well for one to let folks have what they wants." And so, perhaps, it is well, if not inevitable, that what we call education should be what it is. I am going to indicate to you some of the faults I have to find with current education, not that I expect any rapid changes will take place, for the business of education is the most conservative business with which men are concerned. First, let me remark on this peculiarity of Americans: with us education is a passion. There is no interest which is so dear to the heart of our average American as education. We can raise money for almost any kind of a scheme in education. On the whole I think that has been a good thing, but it has not been without its sinister effects.

Another peculiarity about education is that it is a subject of perennial interest. There are coming on crops of successive individuals and generations who come to the subject as if it were entirely new; as if all that need be learned had to be learned by them; and I think it must be admitted that all they learn is learned by them; they cannot learn from other people. But the fact that our young folks come to the subject of education with such assurance and with such optimism illustrates a general fact with regard to that sort of knowledge we call history.

It is a curious and a depressing fact, when we come to think of it, as an old man like me sometimes thinks about it, that we learn less from history than from any other source of human knowledge. Perhaps you would be inclined to dispute that. But have we not had to witness it? One of the most extraordinary examples in all history is furnished by the Paris Peace Conference. Haven't things been set up temporarily or adjusted at that Conference, as if there had not existed twenty centuries of recorded history? Wasn't that Conference one which proceeded as if we had had no previous experience in international law, or in economics, or in anthropology? I think that furnishes the most striking illustration in the whole history of mankind of the fact that we learn almost nothing from history.

"LAW OF THE CONSERVATION OF IGNORANCE"

Turning now from this more serious aspect of my subject to something which is more humorous: Do we not find this fact illustrated in education? Things go on about the same. Our standard courses of education in the colleges and universities are about the same as they were five or six or seven hundred years ago. We have gone on with very little change; and it is probable we shall go on in much the same fashion. In one of my addresses read at Columbia University I made some reference to this subject, and I said our procedure with respect to education is strictly in accordance with the

*President, Carnegie Institution of Washington.

"law of the conservation of ignorance." If you care to look up the subject, you will find that I have elaborated that statement and explained how it happens. There are good anthropological reasons for the statement we proceed in accordance with the "law of the conservation of ignorance."

EDUCATORS COMPLACENT IN REGARD TO EDUCATION

Let me refer to another aspect of education in general. Is there anything concerning which we, as educators—and now I speak as an ex-professor and as an ex-dean—is there anything with regard to which we are more complacent than we are with regard to education? And is it not now being sounded from a thousand platforms? There must be a thousand degree-giving establishments in the United States. From a thousand platforms we may now hear it said that "education makes the man." No proposition can be more nearly wrong than that. I flatly contradict all such statements. Yet we listen to it from year to year with the utmost complacency, with a spirit of serene opacity. Nothing can shake our confidence in our systems of education. Our confidence in education is perhaps most strikingly illustrated, if quantity of noise is a measure, by our monthly, semi-annual and other dinners—alumni dinners. Who has not attended a number of these, and who has not discovered in them a striking similarity to Mr. Bryan's brief description of an old-fashioned Jeffersonian or Jacksonian dinner? When we get together on these occasions, some sing, some dance, some speak, but most of us whoop like wild Indians, with a degree of confidence which shows that we have not the slightest pangs of conscience with regard to what we call education.

MANY HUMOROUS ASPECTS TO "EDUCATION"

But why raise any such questions as these now? This, of all times, is perhaps the most inappropriate occasion to raise a question concerning the curricula; even the curricula of engineering schools, or questions with regard to the conflict of study, or questions with regard to the requirements for degrees. I would be the last to raise any doubt concerning these, because all such technical matters have been settled with a high degree of exactness by our academic friends. They have got the number of points a man or a woman must make down so fine that they express them to four significant figures. It must be evident, then, that it is nearly useless to inquire into these questions, because it must have been settled by our teachers and by the heads of our colleges and universities just what is necessary to make an educated man. Nevertheless, to an old fellow like me, who has been both inside and outside these camps, there are many things that tend to make one laugh, and I trust that whatever I may have to say or have said in criticism of education will not be taken too seriously. I am sure of this, that whatever I say will produce only the slightest effect; yes, an effect which will be purely ephemeral. Nevertheless, there are some very funny things to be found in education; some fallacies that any hard-headed student could easily puncture. But I am disposed to pass these matters over, partly because we engineers have a society for the promotion of engineering education, which has also settled all these points. Yet I think you will agree with me that in spite of all the energetic and active work that society has done, we are not turning out any better engineers now than we turned out

fifty years ago. Do you ask the question why it is that we are not turning out any abler men now than we did fifty years ago? Well, I think it is worth while for us to ask and to try to answer that question.

Here is another question raised by my friend President Eliot, emeritus of Harvard, who created quite a stir in military circles a few weeks ago when he stated that the selection of the men for the work of the Naval and Military academies was not good. I think that statement is obvious. If you wanted to select a good able body of engineers, you would not ask Congressmen to name the men to become graduates of these great schools. Look at the product, however. You must judge institutions and organizations by their products and not by any more refined method. I agree fully with Dr. Eliot, but at the same time I think both parties are right. Where is the paradox? There is a paradox, and it leads me to come to my first point concerning education.

Here is my first proposition: Education does not consist in studying certain things. It consists rather in studying some things thoroughly well. And then my next proposition is that our boys and girls turn out fairly well from educational establishments, not by reason of them, but in spite of them.

The important factor which we educationalists have from time immemorial overlooked is that of heredity; what a man will be when he goes through this, that or the other college depends far less upon the college than the man's inheritance. To put the case in another way, we only need to refer to the formula for the generation of a gentleman furnished by Oliver Wendell Holmes. You know Holmes said, "If you want to generate a gentleman, you must begin 400 years before he is born." Well, so it is in education. Our boys and girls turn out fairly well from the colleges and universities, not by reason of them, but in spite of them. They turn out well because they are on the average of good stock, and that explains why it is that the men from the schools of West Point and Annapolis are, on the whole, able and praiseworthy men.

THOROUGH TRAINING NEEDED FOR SPECIALISTS

It would be easy to cite many illustrations of the fallacies to which I have referred. You know our old and dominating predecessors in the educational world—namely, the humanists—claim that a man, in order to be educated, must study certain things, and particularly certain things in strictly limited quantities. For example, if he pursue mathematics beyond the elements of algebra and the elements of Euclidean geometry, he is stigmatized by our friends and humanists as a narrow specialist. There is something very ridiculous about that common phrase. I think it would be more logical and more polite to say that the training of the specialist—I don't mean the dilettante, but the specialist who knows more than other people about a subject—must be broadly liberal in order that it may be minutely special. And as to that more general proposition I referred to, that "education makes the man," I think it ought to be replaced by this proposition. It is very simple, perhaps too simple—Man makes the education. That is all there is to it, when we come to sift it all down and let the wind out of it. What a man is will depend chiefly upon his industry and upon the capacities which he has inherited from his forefathers.

But some of our critics with regard to engineering education have special charges to bring against students

of engineering. It is alleged they are not only narrow specialists, but that they do not know English; they do not know how to pronounce their own language; they are unable to write their own language. Now, all that is true. It is worse than that. It is a truism and hence a platitude, because there are very few people, however they may be educated, who can speak the English language correctly, or speak any language correctly, and there are very few who can use it with skill. Some of my friends have heard engineers make some very serious mistakes which they would not have made if they had known a little of Greek. To take an example as an illustration, a very little knowledge of Greek would enable a man to say "aéroplane" instead of "air-e-o-plane"; but a much less knowledge of spelling would enable him to know the same thing; and as anybody who pays attention may see, there are about as many who have studied Greek who make this vulgar error as there are those who have not studied Greek. Similarly, in these days we hear much said about science and research, but, as you know, this word research is almost universally mispronounced. It is one of the 25,000 words that are commonly mispronounced. We in our American impetuosity have advanced the accent of that word to a position not yet approved by the lexicographer. But I find that people who have studied Greek and Latin, and who have had all the advantages of classical learning, are about as apt to use "re' search" as other folks. So I conclude that the correction for these errors is not to be found in studying certain things, but is to be found in the slow and painful process of generating men and women who will give attention to words. If a man is a good speller he must give attention to the spelling of words. No amount of study in Latin or Greek or Sanskrit or Choctaw will help him very much. So, if a man is going to be successful as a lawyer, as a doctor, as an engineer, his success will not depend upon his having studied certain things, but it will depend upon the degree of attention which he gives to the things which are before him, concerning which he needs to know.

A short time ago I had a humorous illustration of the serene confidence of a good friend, a humanist, in his learning when he stood alongside an automobile and awaited the opening of the hood to look in on that physical laboratory which we now call the engine of an automobile. He had never given any attention to such subjects, and he was very glad he had a negro chauffeur who did know a little about it. Something had gone wrong with the engine, and it was necessary to find what was wrong. Well, after pacing up and down alongside the hood of the automobile, he turned to me and said, "*Ultra vires*"! Undoubtedly what needed to be done to that engine was beyond him. That illustrates how easy it is for us to be content with little knowledge of some things and to imagine ourselves lords of the universe.

I have two or three faults to find with our engineers. You know that a long time ago John Stuart Mill emitted in one of his books that aphorism, "A man ceases to be progressive as soon as he feels that he is king of his company." Now, during the past fifty years, the engineers have made extraordinary progress. They have come into their own, and some of them have come to feel their sufficiency, and what I fear is that some of us are in danger of making the same classic errors made by our friends the humanists. I occasionally hear some of our engineers assert that if we could

only have the affairs of the world turned over to us we could make them go a good deal better than they are now going; and while there is much truth in this, I suspect there is some degree of error in it, and that having seen a number of classes of predecessors fall into this crass error, it would be well for us to take note of it and try to avoid it in the engineering profession.

In line with that, I would like to say that one fault I find with our schools of engineering now is that they are devoting very little time to research. I think it is a characteristic fault of the schools of engineering in our country that they are willing to take what they can get from other sources, and not cultivate a capacity for original investigation, and have that sort of progress which comes from research. There are a few schools in the United States—and there are individuals—who during their leisure time carry on important researches, but I do not think there are any more such today than there were forty years ago.

This is especially to be regretted at this time, because now is the time of great opportunities for the American engineer. I would like to see a school, or a high school of engineering perhaps we should say, after the French model, for the prosecution of engineering studies, something comparable with the Ecole Polytechnique of Paris. Some of you may not be aware of the fact that a very considerable proportion of the leading engineers in the history of the world have come from the Ecole Polytechnique. Great names are connected with that school. Going back 100 years ago, there were Lagrange, Laplace and Poisson, who laid the foundations of mathematical physics; then a little later came that great aggregation of engineers beginning with Navier, who laid the foundations and built the superstructure of that extraordinary branch of mathematical physics which we call the theory of elasticity, a branch of mathematical physics far and away greater than Einstein's theory, which has attracted so much attention in the past six months.

Now, the thing I want to call your attention to, and especially you young men with whom the future of engineering education largely rests, is that we need to have in our country somewhere, somehow, a great school for theoretical study, which may become comparable with the Ecole Polytechnique. This is not only a great opportunity, but a great duty before us.

A Study of the Hardness of Glazes by the U. S. Bureau of Standards

An attempt is being made to differentiate the different glazes applied to clay products according to their hardness by tests similar to the Brinell test commonly used for metals. The hardened steel sphere used in the Brinell machine is replaced in this case by a conical steel point, the penetration of which into the glaze under high pressure is an index of the hardness of the material. This penetration is measured by means of a micrometer microscope. The pressures employed for forcing the point into the glaze are quite high and have been as great as several hundred thousand pounds per square inch. Although the test has not yet been brought to a satisfactory status, it has differentiated between the several types of enamels and glazes examined. Thus enamels are punctured under fairly low pressures while high-fire porcelain glazes are exceedingly resistant, and white ware glazes occupy an intermediate position.

The Manufacture of Lime for Chemical and Metallurgical Purposes*—III

Methods of Heating Rotary Kilns—Description and Comparison of Pulverized Coal and Producer Gas Installations—Boilers in Series With Kiln—Power Consumption—Cost Data†

BY RICHARD K. MEADE

PULVERIZED coal, producer gas, natural gas and oil are all employed for heating kilns. Localities where natural gas can be used are few and the cost of oil at the present time is prohibitive in most sections of the country, so the fuels generally available are pulverized coal and producer gas. Natural gas is the most convenient fuel and producer gas the most troublesome. Oil is a very convenient fuel to use and the installation also costs less, except where very large storage tanks have to be provided. When oil is used for a fuel, the apparatus necessary to heat the kiln is similar to that required for heating a boiler with this fuel. Almost any type of burner which will atomize the oil and give a conical flame will work satisfactorily. The writer has used Rockwell, Hauck and Kirkwood burners with success. He has also obtained equally good results with a burner which he had made up from his own design out of ordinary pipe and fittings. In all of his installations, he has employed air at from 30 to 40 lb. pressure not only for atomizing the oil but also for forcing it to the burners. In his system there are, in addition to the main storage tank, two small supply tanks, each of which will hold a supply of oil sufficient to last the kiln for from four to six hours and which are capable of withstanding a pressure of 100 to 125 lb. The two tanks are used so that one will be in service while the other one is being filled. The oil is forced from these tanks to the burner by means of compressed air, just as acids are lifted. The writer's experience has been that high-pressure air atomizes the oil better than low-pressure air and the use of air to force the oil to the burners does away with the oil pumps and allows one apparatus to do the work of two.

Owing to the difficulty of securing oil cheaply in most localities, the average lime manufacturer, as I said, will have to decide the question of whether he will use pulverized coal or producer gas for heating the kiln. There are some points in favor of each. Producer gas will give the purest quality of lime. Pulverized coal, on the other hand, will be more economical and easier to handle.

PRODUCER GAS

Producer gas burns a nice clean lime. The temperature of the flame obtained is ample to burn good chemical lime and if the producer is a good one and is well taken care of, fairly uniformly burned lime, free from core, will be obtained. Producer gas, however, varies with the operation of the producer. The hand-fed, hand-rabbed producers give a gas the quality of which depends very largely on the man who operates

them. When such a producer is freshly charged with coal there is a rush of gas through the furnace. The gas then gradually decreases in calorific power until the next charge of coal is put in the producer. Automatically stoked and fed producers operate much more smoothly and if at all well handled this objection is practically eliminated.

The producer should be located under a bunker so that the coal may be fed directly into the hopper of the former. Arrangements should also be made for removing the ashes conveniently. The producer should be located near the kiln so that no more heat will be lost by radiation than is absolutely necessary. The piping should be so arranged that the flues can be cleaned easily. Usually each kiln has its own producer or producers and no valves are inserted between the kiln and producer, the rate at which the producer is operated

FIG. 7. PRODUCER GAS INSTALLATION

controlling the flow of gas to the kiln. Where two or more small kilns or other furnaces are heated from the one producer, etc., valves will, of course, be necessary. In the event a valve is not used, a sand damper or some means of shutting off entirely the producer from the kiln should be provided so that the lining of the latter may be repaired when desired without allowing the fire in the producer to go out. Fig. 7 illustrates the installation of a gas producer in connection with a kiln.

As an 8 x 125-ft. kiln will require from twenty to twenty-five tons of coal to heat it, or a gasification of about 2,000 lb. of coal per hour, it will be seen that one kiln is large enough to have its own producer or producers and one large kiln is always to be preferred to several small ones.

The largest mechanically stoked producers will take care of from 3,000 to 3,500 lb. of coal per hour, or

*Read before the American Institute of Chemical Engineers, Montreal, June 28, 1920.

†For Parts I and II see CHEM. & MET. ENG., vol. 23, Nos. 17 and 18, Oct. 27 and Nov. 3, 1920, pp. 841 and 873.

about thirty-two to forty-four tons per day, but much smaller producers can be obtained with the automatic feed and stoking arrangement.

About 0.4 lb. of steam will be required to operate the producer for each pound of coal gasified. This is equivalent to approximately one boiler-horsepower per ton of coal gasified in twenty-four hours. Or an 8 x 125-ft. kiln would require twenty to twenty-five boiler-horsepower.

One man per shift can take care of a mechanically stoked producer with the help of another man part of one shift to get coal into the bunker, take away the ashes, etc.

I estimate that the cost of producer gas in a well-equipped plant is approximately as follows, figuring on a producer which will gasify 2,000 lb. hourly:

Attendants, 1 man @ \$4, 3 shifts	\$12 00
Attendants, 1 man @ \$3 20, 1 shift	3 20
Steam, coal @ \$5.....	6 00
Supplies, repairs, etc.....	5 00
Cost per 24 tons of coal gasified	\$26 70
Cost per ton	\$1 09

Added to the above should be the losses from the producer. With smaller producers, cost of attendance would, of course, be more per ton, which would raise the cost of the gas.

COMPARISON OF PRODUCER GAS AND PULVERIZED COAL FIRED OPERATION

The advantages which pulverized coal has over producer gas for heating rotary limekilns are, first, the much more uniform rate of supply of fuel to the furnace, as where proper feeding devices are used there is a continual supply of fuel to the furnace at a regular and uniform rate, and this fuel is, of course, of the same thermal value at all times and does not vary in this as does gas. Second, with powdered coal the loss of carbon due to that remaining in the ash is avoided. Third, it is possible to burn powdered coal with almost the exact quantity of air necessary for combustion, which is not possible with producer gas. This means a higher flame temperature and a saving of fuel. Fourth, in the producer there is a loss of coal due to carbon completely burned to carbon dioxide. A certain portion of this loss is of course conserved as sensible heat in the gas and is utilized provided the producer is set close enough to the kiln to cut down radiation losses.

The efficiency of a producer is seldom greater than 85 per cent and is generally less than this compared with pulverized coal.

Experiments which the writer has made indicate that when pulverized coal is used about 40 per cent of the ash of the fuel enters the lime. Assuming, therefore, that 450 lb. of coal is required to burn a ton of lime and that the ash amounts to 10 per cent of the weight of the coal, one ton of lime would contain 18 lb. of ash, or about 0.9 per cent. I am giving herewith two analyses showing lime burned with pulverized coal con-

taining 11 per cent ash and what the same lime would be burned with producer gas.

A larger amount of ash will be retained by lime in which there is a lot of fine material, such as where the fine limestone dust has not been screened out, than will remain where the dust is screened from the coarse stone. The dust seems to catch and hold the ash rather than to allow it to be carried away by the draft of the kiln.

The cost of pulverizing twenty-four tons of coal daily is approximately as follows:

Drying the coal — 0.2 tons coal @ \$5	\$1 00
Attendants — 1 man, 1 shift, 8 hours @ \$4	4 00
Grinding 400 kw.-hr. @ 2c	8 00
Supplies, repairs, etc.....	4 00
Cost of pulverizing 24 tons	\$17 00
Cost per ton	\$0 71

It is hardly necessary in this paper to go into the various methods for pulverizing coal. The subject has been dwelt on quite extensively in technical literature the last few years.¹

PULVERIZED COAL INSTALLATIONS

Sufficient to say, two general systems may be employed for heating the kiln with pulverized coal. One system in which the coal is pulverized and blown into the kiln at the same operation and the other in which the coal

FIG. 7. ROTARY KILN HEATED BY AERO PULVERIZER

is pulverized in a separate plant, the pulverized coal conveyed into a bin at the kiln and fed from this into the burner as desired.

Fig. 8 shows the former installation in which an "Aero" Pulverizer is used. This latter consists of a series of paddles which revolve about a horizontal axis in circular chambers through which air is drawn by means of a fan on the same shaft as the paddles. The coal is pulverized by being thrown against the walls of the chambers by the paddles and is drawn out with the necessary air for combustion and blown directly into the kiln through a pipe which extends directly from the pulverizer to the kiln. This pulverizer is supposed to work on damp coal and with Eastern coals has given fairly good satisfaction without drying the coal. With some of the coals in the Middle West, however, the experience has not been so good. The Aero requires about 18 hp.-hr. (13½ kw.-hr.) per 1,000 lb. of coal pulverized, or with ordinary fuel consumption about 7½ hp.-hr. (5½ kw.-hr.) per ton of lime produced. It should be remembered in comparing this power with that required by other machines that the above includes power necessary to blow the coal into the kiln, etc. This machine may be looked upon as a cheap method of

COMPARISON OF LIME BURNED WITH PRODUCER GAS AND PULVERIZED COAL

	Analysis of Lime Burned With	
	Pulverized Coal	Producer Gas
Silica.....	2.44	2.10
Iron oxide and alumina	1.15	0.80
Lime.....	94.33	95.00
Magnesia.....	1.22	1.24
Loss on ignition	0.86	0.86

¹See Meade, *Transactions of American Institute of Chemical Engineers*, vol. 1, p. 98.

heating the kiln with pulverized coal rather than as the most efficient, as it does not pulverize the coal very finely.

The best method of preparing the coal and the one which would probably be used by a large lime plant would be to pulverize the coal with either Raymond or Fuller mills and convey it into a suitable storage bin, from which it would be fed to the kiln as required. Fig. 9 illustrates this system, a Raymond mill being used.

Either one of these two pulverizers will require the

FIG. ROTARY KILN WITH SEPARATE COAL PULVERIZING PLANT

coal to be crushed to about 1 in. and to have been dried. The Aero Pulverizer will also require that the coal be reduced to 1 in. For crushing the coal a set of rolls is usually employed and the drying may be done in any of the accepted types of rotary coal driers.

The coal bin should hold sufficient coal to last the kiln sixteen to twenty-four hours so that the pulverized coal plant need not be operated more than one shift. The coal is fed out of the bin at a uniform rate by means of a worm, the speed of which can be altered to give the desired amount, and dropped into the burner. Either steam or high- or low-pressure air may be employed to blow the coal into the furnace. Low-pressure air at 6 to 10 oz. from an ordinary blower is usually employed, about 50 per cent of that necessary for combustion being so supplied.

BOILERS IN SERIES WITH KILN

The waste gases leave the kiln at about 1,300 deg. F. and hence contain a large part of the heat liberated by the burning of the fuel. This heat can be successfully utilized in boilers, as has been done in the cement industry where an efficiency of 70 per cent has been obtained. The weight of gases usually amounts to between 6,500 and 7,500 lb. per ton of lime produced. The heat in the same will, therefore, be approximately 2,275,000 B.t.u. This is about 40 per cent of the total energy of the coal burned, the remaining 60 per cent being dis-

tributed about as follows: Decomposition of the limestone, 54 per cent; radiation from the shell, 6 per cent. Of this waste heat 70 per cent has been successfully utilized by waste heat boilers, or about 1,500,000 B.t.u. per ton of lime produced. This is equivalent to 1,550 lb. of steam at and from 212 deg. F., or 45 boiler-horsepower (hours). A kiln burning four tons of lime per hour, therefore, would be good for about 180 hp. In the new lime plant of the Eastern Potash Corporation, designed by the writer, boilers are being installed. In most chemical plants where steam is needed for evaporation the plan should certainly

be employed, as not only power enough to operate the kiln can be obtained but considerable in excess.

FUEL CONSUMPTION

The fuel requirements of a rotary kiln are from 2,800 to 3,500 B.t.u. or 400 to 500 lb. of coal per ton of lime, 37 to 45 gal. of oil per ton of lime, 500,000 to 625,000 cu.ft. of natural gas per ton of lime.

This is better than can be accomplished with the best hand-fired kilns and but slightly less than that claimed for the best types of gas-fired kilns. The quantity of fuel required depends, just as in the case of the vertical kilns, upon the nature of the stone, the kind and quality of the fuel, the skill of the operator and the kiln itself. The most economical kiln is one in which

the ratio between length and diameter is greatest. That is to say, of two kilns having the same diameter but different lengths operated under the same conditions, the longer kiln will have the greater fuel economy (and incidentally the greater output also).

If we deduct the fuel required to produce this power from that required to burn the lime, the efficiency of the rotary kiln will far exceed any other type. To produce 180 hp. about 720 lb. of coal per hour will be required, while to heat the kilns 1,800 lb. of coal per hour will be required, leaving 1,080 lb. of coal charged against the lime burning—or 7.4 lb. of lime per pound of coal.

Where the gases from the kiln are needed in the chemical process they can be drawn off from the kiln stack by means of a fan. Generally speaking, the gases from a rotary kiln are not quite so rich in carbon dioxide as those from a vertical kiln due to the leak through the annular space where the kiln revolves in the stack chamber. By proper arrangements for closing up this opening as much as possible, a gas containing about 24 per cent carbon dioxide on an average can be obtained. The waste gas always contains dust consisting of particles of limestone and lime and, if pulverized coal has been used for burning, the ash of this coal. The gases may be cleaned practically free of this by the use of water sprays, gas washers, etc.

One man can attend to the kiln provided the stone is placed in the feed bin for him. If there are more than one kiln, one man and one assistant can attend

to as many as three kilns. If the Aëro is employed to pulverize the coal, the kiln tender looks after this also. The coal, however, should be placed in the bin above this for him, so that all he has to do is to see to the proper operation of the kiln, cooler and pulverizer. Any intelligent man can be broken in to operate the kiln in a satisfactory manner.

POWER CONSUMPTION

The power required to operate a rotary-kiln plant will be about as follows per ton of lime produced:

	Hp. hr.	Kw.-hr.
crush limestone	2 50	1 9
revolve kiln, feeder, etc.	4 25	3 2
revolve cooler	1 25	1 0
pulverize coal, separate plant	5 50	4 1
feed and blow coal into kiln	2 00	1 5
pulverize coal, Aëro system	8 00	6 0
miscellaneous, stone elevator	1 00	0 8
Total where pulverized coal is used	16 50	12 5

Repairs to the kiln are light and consist in an occasional renewal of the lining at the lower 20 or 25 ft. of the kiln. The lining of the upper part of the kiln will last for many years, but in the hottest part of the kiln the lining must be renewed every six to nine months, although a careless attendant can burn out a lining in a few weeks' time. An allowance of 25c. per ton will easily take care of repairs to the kiln, relining

when necessary and the lubricants, provided the kiln is properly handled. Under existing conditions a rotary-kiln lime plant of the best construction will cost approximately \$950 per ton of lime produced per day. This figure includes a steel building entirely over the kiln and a pulverized coal plant or mechanically stirred producer. Where an Aëro Pulverizer or oil fuel is employed the cost is slightly less. It is not absolutely necessary to cover the whole kiln with a building. If this is not done, of course, the cost will be reduced.

The cost of producing lime in a rotary-kiln plant in the Middle Eastern States at this time is about as shown in the accompanying table. The first column rep-

COST SHEET OF A ROTARY-KILN LIME PLANT

Stone, 2 tons	\$1.50 to \$2.50
Coal, 0.2 ton	1.00 to 1.50
Labor	.20 to .60
Power, 15 kw.-hr. at 2c.	.30 to .45
Repairs, supplies, etc.	.25 to .35
Total	\$3.25 to \$5.40

resents cost with an output of 100 tons daily, stone quarried at the plant and a coal at \$5 per ton. The second column represents cost with a 30-ton plant where stone is purchased and coal costs \$7.50 per ton.

Glueing Turpentine Barrels

Turpentine will readily penetrate through the staves of an ordinary wooden barrel. It is therefore necessary to coat the inner surface of the barrel with ordinary glue, which is insoluble in turpentine but readily soluble in water, say naval stores experts of the Bureau of Chemistry, United States Department of Agriculture. Turpentine soon leaks out from a barrel that has been carelessly or improperly glued, as well as from one containing any water, regardless of how well the glue was prepared or applied. Consequently great care must be taken in preparing the glue and applying it to the barrel, and finally also in so filling the barrel with turpentine that no water gets into it.

As a rule, glue makers furnish with their product a formula showing the proper proportions of glue and water. The following formula is recommended by one of the largest producers of animal glue:

Glue, lb.	20
Water, gal.	8
Commercial borax, powdered, lb.	1
Commercial glycerine, lb.	1

The glycerine is added to make the glue more elastic, and may be omitted if the directions for preparing the glue here given are carefully followed.

Late in the afternoon place the quantity of glue required for the next day's work in a perfectly clean jacketed or double-boiler glue kettle, cover with the proper quantity of clean cold water, and let it dissolve slowly to a jelly. When glue prepared in this way is heated the next morning, it dissolves in the water rapidly and smoothly, and has the further advantage of being somewhat stronger than that simply mixed with cold or hot water and immediately heated.

Since animal glue rapidly loses its adhesive strength when it is subjected to a high temperature, it should never be boiled. Glue prepared in a single unjacketed kettle over an open fire will almost certainly become too hot and boil when not watched, or it will not be hot enough to glue the barrels properly without waste. In preparing the glue, then, use a double boiler or jacketed glue kettle. The boiling water in the lower pot heats

the glue in the upper pot to the proper temperature without bringing it to a boil. Do not keep the glue hot longer than necessary. Have the barrels ready to glue as soon as the glue is hot, glue at once, and clean the glue kettle for the next day.

Before glueing the barrel, drive the hoops down moderately tight. Then pour about 1 gal. of the hot glue into the barrel, plug up the bung hole, and sluice the barrel around well, making sure that the glue comes into contact with every bit of the inside surface. Remove the stopper, place the barrel on a rack over the glue kettle, and allow the excess glue to drain directly into the kettle. As soon as most of the excess glue has drained out, take the barrel from the rack, and stand it on one head in a level place. About one-half hour later, drive the hoops down absolutely tight, so that the tension on the hoops all around the barrel will be equal, and let it stand on the same head, thus permitting some of the soft glue still inside the barrel to settle down in the chime, where most of the leaks occur. Allow the barrel to stand, bung open, for several days under a shed, protected from the sun and rain, and then glue again exactly as before, but making sure that the barrel stands on the other head this time. After two days the barrel is ready for use. Barrels glued in this way should give little if any trouble from leaking, provided no water is allowed to get in.

As animal glue is extremely subject to decomposition through the action of bacteria and molds from the air, glue left in an open kettle soon begins to decompose, as shown by its foul odor, thus becoming no longer fit for use. It is, therefore, highly important to keep any left-over glue sweet and clean if it is to be used again. The unused glue should be poured into a can which may be tightly covered and stored in a cool place, and the pot thoroughly cleaned. Fresh glue is ruined if put in a filthy pot containing decomposed, foul-smelling material. The borax recommended in the formula is to help keep it sweet, and should be dissolved in the glue when ready for use.

Electric Furnace Refractories*

A Brief Description of the Raw Materials Now Available for Highest-Grade Brick, Together With a List Showing Recommended Refractories for Melting the Different Metals and Alloys, and Practical Hints on the Care, Storage and Laying of Roofs, Hearths and Linings

BY A. F. GREAVES-WALKER†

ONE of the most important problems facing manufacturers and operators of electric furnaces at the present time is that of refractories for linings and roofs.

The greatest advancement in furnace design and usage came during the period of the war. From the standpoint of the refractories manufacturer this was unfortunate, as the conditions prevailing in the industry at that time prevented him from giving the electric furnace the attention it deserved. Not only were the sources of some of the best raw materials cut off, but added to the great problem of supplying an ever-increasing demand in all metallurgical and chemical lines were many new ones presented by nearly all users of refractories. It was not surprising, therefore, that the electric furnace received what must have appeared to be scant attention.

In discussing the subject of refractories it will be well to bear in mind that electric furnace design has been entirely in the hands of electrical engineers. Furnaces have been designed, built and sold before the refractories engineer has even had an opportunity to see whether satisfactory linings and roofs could be made up or not. In some cases conditions imposed by the designer were impossible, but under the conditions there was no other course but to make the best of a bad job. It must be remembered too that not only was the refractories manufacturer called upon to supply satisfactory linings and roofs for the standard makes of furnaces, but during the war dozens of "home-made" furnaces were built and put into operation, each one of which presented its own problems.

RAW MATERIALS

The manufacturer of refractories is always limited by his raw materials, earths or minerals in nearly every case. It is therefore impossible to produce finished products having qualities that the raw materials do not possess. In other words, he is bound within comparatively narrow limits.

So far as electric furnace refractories are concerned, the following materials are available:

Basic: Magnesite, dolomite, zirkite, alundum or carborundum, bauxite.

Neutral: Chromite, zircon, carbon, fireclay.

Acid: Silica.

MAGNESITE

Magnesite is a carbonate of magnesia and is found naturally in two forms: The amorphous or massive, and crystalline. The amorphous type is entirely unsuited for refractories purposes, but during the war, after the Austrian ore was cut off, this was the only material available, the source of supply being Cali-

fornia. The fact that the metallurgical industry was forced to use this unsuitable material accounts for much of the trouble encountered during the war period. In 1917 the crystalline magnesite from Washington began to come into use. This material is much like the Austrian, except that it is higher in lime and silica and lower in iron. In order to give it a bond it is necessary to add iron. This addition, together with the higher silica content, reduces its fusion point and basicity and lowers its efficiency considerably in comparison with the Austrian mineral. In recent months the Austrian ore has been gradually coming into the country in increasing amounts, but as yet has not reached a point where the supply nearly equals the demand.

There can be no question whatever that in electric furnace work the Austrian material is so superior as to be in a class by itself, and as soon as there is a sufficient quantity imported to supply the demand much of the electric furnace user's trouble with basic linings will disappear.

Magnesite is prepared for use by first dead-burning the crude ore, or driving off all of the CO₂. This is done in rotary kilns at a temperature of approximately 3,000 deg. F. When the material comes from the kiln it is sintered and in the form familiar to furnace men as dead-burned grains.

In manufacturing brick and shapes this dead-burned grain is ground and molded either in a heavy press or by hand. Undoubtedly the press-made product has very great advantages in electric furnace work on account of the great density obtained. When the product is well made and hard burned it will show practically no slag absorption. In cases where special shapes in small quantities or shapes impossible to make up on a mechanical press are required the hand-molding process is used. Magnesite is not suited to the manufacture of difficult or very large shapes, due to its tendency to crack or "squat" in the kiln at high temperatures. After coming from the molds the product is dried and burned in standard brick kilns and is then ready for shipment.

FUSED MAGNESIA

Fused magnesia has found use recently in the linings of induction furnaces. Little is yet known of its commercial value, but experiments would indicate that it may become extremely useful for certain purposes.

Calcined or dead-burned magnesite is fused electrically in manufacturing this product.

CHROMITE

None of the neutral refractories have come into wide use in electric furnace work.

Chromite, or more commonly "chrome," as the sesquioxide of chromium (FeO.Cr₂O₃) is called, is the best known of the neutrals. Since the Turkish, Grecian and

*Paper read before the Columbus meeting of the Electric Furnace Association, Oct. 7, 1920.

†Production Manager, American Refractories Co., Pittsburgh, Pa.

Rhodesian ores were cut off by the war, this country has had to depend upon the deposits of California and Oregon. Most of these deposits produced ores that ran only between 30 and 40 per cent Cr_2O_3 and contained a combination of other elements which gave them an extremely low melting point. The failure of brick made from domestic ores to stand up has caused the gradual discontinuance of their use. At the present time the foreign ores are coming on the market and a much better product, in fact one equal to or better than the pre-war product, is being manufactured.

ZIRCON

Zircon is here classed as a neutral, although it is questionable whether or not it should be considered as in the acid class. Its use is still in the experimental stage, but the few refractories that have been produced have been turned out by the same processes as used for magnesite.

Zircon does not have so high a melting point as zirkite, but it does not produce the carbide under reducing conditions in the presence of carbon. It is questionable whether it will ever come into general use.

CARBON

Carbon is used as a lining for special purposes, such as in the production of ferromanganese. The amorphous carbon is mixed with the binder, such as tar, and molded into shapes in presses or by hand and then burned in standard kilns. Very naturally the use of carbon refractories will be limited.

DOLomite

Dolomite is a carbonate of lime and magnesia. Before using it is usually dead-burned in rotary kilns and when properly prepared is mixed with a small percentage of iron, which aids its bond. Because of its high lime content it is unstable and will slake into powder upon exposure to damp atmosphere. Thus it is impossible to make dolomite brick and this refractory is, therefore, used only for patching bottoms.

ZIRKITE

Zirkite is a carbonate of zirconium. Zirkite brick and shapes are made by the same process as that used in the manufacture of magnesite brick. While zirkite is classed as a base, the ore has usually been so high in silica as to give it a neutral or acid reaction. It has not as yet come into wide use as a refractory and may be said to be still in the experimental stage. It is rather questionable whether this refractory will ever come into wide use on account of its affinity for carbon at high temperatures. Under such conditions it forms a carbide which has a low melting point.

CARBORUNDUM AND ALUNDUM

Carborundum and alundum would undoubtedly become very popular as electric furnace refractories were it not for their high cost. They have a very high melting point and low coefficient of expansion. Heretofore their use has practically been limited to jamb tile and roof brick. In jambs they have been quite successfully used.

BAUXITE

Bauxite has been little used for electric furnace work, due principally to its general failure in metallurgical work. Some other high-alumina refractories have found a little favor in cases where furnaces were turning

out special products, but none of this class have been able to replace magnesite in basic practice.

Products made from these materials are usually hand molded, dried and burned in the ordinary manner.

FIRECLAY

Fireclay is the most widely used of all refractory raw materials and naturally refractories made from it find their greatest use in the metallurgical field. Fireclay products have not, however, become popular in electric furnace work, due principally to the high temperatures encountered. While there is little difference between the melting points of high-grade fireclays and ganister, the fireclays begin to soften considerably below their melting point and as a rule have a high slag and metal absorption.

Fireclays or clays used for refractories purposes are found in almost every state in the Union.

The methods of manufacture vary with the type of clays and their proposed use; fireclay brick are made by the auger machine, dry press, soft mud machine, and hand methods. They are dried and burned in ordinary brick driers and kilns.

SILICA

Silica or ganister rock is used for the manufacture of the well-known silica or acid refractories. Deposits containing the proper silica content and having the required physical properties are located principally in Pennsylvania, Wisconsin, Alabama, Montana, Colorado and Utah. The rock from Wisconsin and Pennsylvania has been used almost altogether in electric furnace refractories and of the two the Wisconsin rock seems to give the best results, especially in roof work.

Silica refractories are made by the hand process and dried and burned by ordinary methods.

RECOMMENDED REFRACTORIES FOR ELECTRIC FURNACES

The selection of the proper refractories for electric furnace work depends on several factors:

- (1) The product of the furnace.
- (2) Whether basic or acid process.
- (3) The type of furnace.
- (4) Whether furnace is operated continuously or intermittently.

In considering the first of these factors—the product of the furnace—it will be well to take up first the hearth and lining recommended for various products.

Steel Ingots and Castings.—Magnesite when high-grade steels are required. Silica when there are no special requirements on steel or when selected pure scrap is used.

Alloy Steels.—Magnesite exclusively.

Ferromanganese.—Magnesite or carbon.

Ferrochrome.—Magnesite or chrome.

Ferrosilicon.—Silica.

Cast Iron.—Fireclay brick when low temperatures are used and cupola practice simulated. Silica when high temperatures are used in rapid melting. Magnesite on irons of special low sulphur and phosphorus requirements.

Copper.—Magnesite on bronze scrap or pig containing lead. Silica or magnesite on refined pig (over 99 per cent Cu) and pure scrap.

Bearing Metal (Copper, Lead, Tin, Antimony).—Magnesite, as low as possible in SiO_2 , especially with high lead content.

Monel Metal (Copper, Lead, Zinc, Tin).—Magnesite preferably, but silica can be used.

Bronze (Copper, Zinc, Tin).—Silica preferable, but magnesite can be used, where zinc is not too high.

Lead.—Magnesite exclusively.

Silver.—Silica.

Aluminum and Alloys.—Magnesite exclusively.

The recommendations are based upon the best practice of this country and Europe. There are naturally some cases where other linings would give better service, as the conditions in different furnaces can be so easily varied.

REFRACTORIES FOR STEEL FURNACES

In the steel foundry the selection of the lining is, of course, limited to either silica or magnesite, depending upon whether the acid or basic process is used. This applies also to any other metal or metals.

The refractories used can be varied to suit the type of furnace only in a very limited way. In the bottom contact furnace, for instance, a metal cased magnesite brick has been tried out to a very considerable extent. The idea was that the metallic casings would aid the current flow from the charge to the contact bars on the shell. So far as it went the idea was good, but as the cases were filled only with dried dead-burned magnesite and not reburned there was little or no resistance to the molten metal penetrating to the shell. Far better results can be obtained by using burned brick and inserting between them thin metal sheets or strips.

In some types of furnaces a hot spot is developed on one section of the wall due to the location of the electrodes. In such cases, when a magnesite lining is used, a section will sometimes fall out when the furnace is tilted. This trouble can often be overcome by inserting a patch of silica brick in the hot section.

The continuous or intermittent operation of a furnace has a very important bearing on the refractories. This is especially true of the roof, which will be discussed later, but also applies to a lesser extent to the hearth and lining.

Silica and magnesite are both affected by rapid changes of temperature, but the latter to a much greater extent. In a basic operation it is, therefore, unwise to carry magnesite above the slag line, as the spalling action on silica will be much less.

When a furnace is operated intermittently, especially with prolonged shut-downs, the use of dolomite in any great thickness is unwise because it will slake to a powder upon exposure to the atmosphere.

ROOF BRICK AND ITS LAYING

In the matter of roofs the furnace man is practically limited to the use of two refractories—silica and fireclay.

A roof properly built of high-grade silica refractories will undoubtedly give longer life than any other provided the furnace is operated continuously, but nothing will prevent spalling and short service when the furnace is operated intermittently. This latter fact has been extremely hard to impress upon the furnace users, with the result that the refractories manufacturer has been blamed for many roof failures for which he was not responsible. It is extremely hard to heat up an electric furnace slowly and avoid spalling the silica brick, and it is therefore necessary to determine by experiment whether a fireclay roof will serve better under the conditions. It is simply a question of whether

the fireclay will melt or the silica spall faster, a matter easily determined by a comparison of the number of heats.

Most of the roof spalling that has been encountered in furnaces that have been operated continuously has not been due to temperature changes but to faulty construction. When a roof is laid up, either of shapes or 9 in., the proper expansion joints are usually left. On the first heat the wood expansion strips are burned out and the top is then thoroughly grouted with silica cement. This grouting fills all open joints and when the roof cools down the brick or shapes settle down into a fairly tight job. The expansion joints have practically disappeared, either through the settling together of the brick or by being filled with grout, and therefore upon the next heat the brick, having no chance to expand, begin to crush one another, the natural result being that the lower or small end is crushed off first and drops into the bath. This crushing or spalling does not take place over the entire roof but only between the skewback and electrode rings. It is in this area that the greatest thrust is encountered. Many efforts have been made to devise a means of overcoming this difficulty, but the only one that has met with success is the Griffin patent. This patent covers a roof containing special shaped brick in the rings between the skew and the electrode rings. Each of these brick has an offset or shoulder near the upper or top side which in practice prevents the grout from penetrating beyond it, thus leaving the original expansion joint free to come and go at the bottom.

In practice this roof is giving splendid results, the life under continuous operation being from 100 to 200 per cent greater than for straight brick.

There is no part of the furnace that receives harder treatment than the roof and no part that presents greater difficulties for fair comparisons. The difference of only a few inches in the distance from slag line to roof will make a very great difference in the life. One instance was noted where a Heroult roof ring was raised 6 in., with the result that the silica roof gave twice the number of heats.

The handling of the arc also has a very considerable bearing on the roof life.

Another very important cause of short roof life has been the lightness or instability of the roof ring. Sometimes this ring has been constructed of such light material that when a roof was picked up to be placed on the furnace the weaving effect was great enough to loosen all of the brickwork, the result being that some of the brick or shapes would drop out entirely, or at least drop down out of place, with the loss of a number of the important expansion strips. Many lining and roof failures blamed upon the refractories have been entirely due to the lack of rigidity in furnace construction.

TREATMENT OF REFRACTORIES

All refractories are injured by exposure to the weather. The manufacturer uses every care to prevent his product from being exposed, only to note that many users pay no attention to this important point. Freezing is very injurious to any refractory, but is probably most damaging to silica brick on account of its porosity. Dampness in itself will not greatly injure a refractory, but the damage is done in using wet brick in a lining and then not taking sufficient time to thoroughly dry them out. There is absolutely no safe rule to follow in

the rate of heating a damp wall. It is a guess at best and the furnace man who uses wet brick should be willing to accept the results if his guess is wrong. Magnesite brick should never be wetted and should be laid up with dry cement. These brick give up moisture slowly, and if it is present and the heat is raised fast enough to convert it to steam, the brick will be disintegrated to a powder. At least 99 per cent of the complaints received by magnesite brick manufacturers on their product are due to the use of wet brick or the attempt to lay them up with a wet mortar.

Not enough attention is paid to proper expansion joints when using magnesite brick. A full $\frac{3}{8}$ in. per ft., or 1½ per cent, should be allowed and it is always the best practice to allow for expansion between brick. This can easily be done by using pasteboard strips.

A special effort should be made to handle magnesite and chrome brick with extreme care, not only because of their high cost but because they are laid up with very small quantities of dry cement and chipped and

broken edges and corners will not make a tight job. Brick should always be laid up with the cement recommended by the refractories manufacturer. Many patching cements and refractory mortars are extremely injurious to brickwork under certain conditions and none now on the market should be used in contact with magnesite brick.

The use of a course of chrome brick between the magnesite and silica has been common practice in metallurgical furnaces, but in the past few years has been found to be unnecessary. The presence of chrome is naturally objectionable when making many steels.

Finally, skill in furnace operation has much to do with the life of the refractories in the furnace walls and roof. The most critical period of the heat is just before the arc is veiled by the froth from the slag. At this time the section of the lining nearest the electrodes is exposed to an intense heat. Close attention by the operator at such times will add many heats to the life of the lining.

Substitute Belting in Germany

BY C. A. HEISE

DURING the war, while Germany was cut off from the world's markets, the want of various raw materials formerly imported from abroad made itself increasingly felt and though, in spite of the blockade, supplies were flowing in from neutral countries they cannot be said to have relieved the situation to any feasible extent. The German industries were thus thrown upon their own resources and immediately set to work on the utilization of all kinds of substitute materials.

Leather for belting was one of the many materials which became scarce and for which the need for efficient substitutes made itself severely felt. Though the pre-war consumption of leather for belting amounted only to $\frac{1}{4}$ per cent, and for packing, etc., to 1 per cent, it should be remembered that practically every available ounce of leather was commandeered by the government for munition and other war industries. The textile industry might have come to the rescue but for its own shortage of raw materials. The need for suitable substitutes having become pressing, extensive experiments with belting made of wood pulp products were carried out; belts built up of wire, with wooden or pasteboard members, similar in construction to a driving chain, were also subjected to extensive tests. Many patents were granted for paper belts reinforced by an interior wire netting, etc., and reports at hand tend to show that on the whole they gave satisfactory results, being particularly adapted for horizontal drive, though it would appear that for agricultural machinery they were less suitable.

USE CONTINUED AFTER THE WAR

With the lifting of the blockade Germany was once more enabled to replenish her depleted stores of some foreign raw materials. The use of substitute belting, however, is being continued because of the depreciation of German currency, which has almost prohibited the purchase of leather abroad.

For decades to come Germany will, for purely economic reasons alone, have to reduce her consumption of imported materials to a minimum while developing

her productive capacity to a maximum. The truth of this statement has already been acknowledged by her manufacturers, with the result that their engineers are beginning to pay special attention to the redesigning and reconstruction of machinery with a view to adapting substitute belt drives. The experience gained during the last few years makes rather interesting reading. The instructions given by substitute-belting manufacturers will doubtless be read with equal interest in America inasmuch as some of them apply equally to leather belting—especially when of poor or medium quality—the careless handling of which is a costly factor in the maintenance of otherwise well-managed shops.

LIMITATIONS IN ITS USE

The difficulties and obstacles encountered in the initial stages were due not only to the lack of experience but to the fact that all available data on belting as contained in engineering handbooks and catalogs were applied to leather belting and could be used only for substitute materials of similar quality. The educational value of up-to-date trade journals was perhaps never more apparent than at this initial stage. Substitute belting proved in all cases inferior in strength to leather and it was accordingly found necessary to increase the standard widths of pulleys. As to crowning of pulleys—a subject on which there was always a divergence of opinion among engineers—it was definitely established that excessive crowning proved rather disadvantageous. Low speeds were also condemned, it being suggested that a speed of less than 3 ft. per second should be avoided, and tests carried out with a view of furnishing data on pulley diameters showed that the efficiency of pulleys having a diameter of less than 8 in. was rather poor. Particular attention has to be paid to proper alignment of shafts and pulleys in order to insure steady and quiet running and avoid transversal movements of the belt. Flange pulleys should not be used, the tendency of the belt to rub against, or crowd upon, the flanges having injurious effects upon the belt. For a similar reason it is suggested that belt shifters should be provided with rollers. Sharp edges on belt shifters or cone and step pulleys should be rounded off, their knife-like action being liable to destroy the best material within a short time.

Berlin, Germany.

Efficient Hydraulic Laboratory Press

The 21-ton hydraulic testing press shown in Fig. 1 is capable of handling an unusually wide range of materials and is quick and convenient to operate.

The base is solid steel, into which the two forged-steel strain rods are screwed. These rods are supported at the top by a cast-iron yoke through which runs a long screw. The screw has square threads and is operated by a handwheel.

The platen slides on brass-bushed bearings on the strain rods. It has a rim around the edge and spout for catching and draining off any juices that may flow over the sides. The platen is cast with a $3\frac{1}{4}$ -in. ram which extends into the steel base and which serves the purpose of a hydraulic cylinder into which a ram works that is forced forward by means of a screw and hand-operating device as shown by the left-hand projection in Fig. 1.

To operate the press the material to be pressed is placed on the platen and the swiveled head on the screw is then screwed down tight against the material. The other screw shown on the lower left of the illustration is then operated, thereby bringing pressure to bear on the liquid that fills the cylinders and forces the main ram upward, thus compressing the material. When the pressure reaches 4,200 lb. per sq.in. as indicated by the gage a total force of twenty-one tons is exerted between the swivel head on the screw and the platen.

Various containers to accommodate different classes of materials are provided. These include two sizes of curb type containers each with steel plates drilled and grooved to facilitate drainage. These plates are used

FIG. 1. HYDRAULIC LABORATORY PRESS

in pairs with the grooved faces together. Another type is the ring or Büchner container. This consists of a series of ten rings bolted together and so grooved and drilled that the expressed juices readily drain. A special plunger fits in the center of the rings on top of the material and the pressure is applied to this plunger. Solid test curb and test ring type containers are shown in Fig. 2. Still another type is the filter pot container which is highly satisfactory for use with substances that are in a liquid or semi-liquid state.

Clearance or daylight space of this press is 20 in.

from platen to swivel head when at its highest point. Inside measurement between rods is 9 in. The press is built by the Hydraulic Press Manufacturing Co. of Mount Gilead, Ohio.

An almost unlimited range of experimental work can be handled in this press, including extraction, filtering, briquetting, extruding and small forming and forcing jobs. In the latter uses a record of the pressure

FIG. 2. CONTAINERS FOR LABORATORY PRESS

required for any operation may be made, since the gage accurately shows the tonnage brought to bear on the material under pressure.

Such materials as flavoring extracts, tinctures from herbs, etc., are representative of the class of materials to which the extraction method would apply. Both the rack and cloth methods and curbs are used in this work.

For briquetting, dies may be arranged to press from one or both sides. Dies for extruding metal and other substances may also be used in this press.

Products that may be tested by the filtering process include dyes, clays, cocoa, oil extraction, etc. For the last, the containers are made very thick so that when heated they retain the heat during the period under pressure.

A Furnace for the Determination of Moisture in Dry CO₂-Free Air

BY J. A. MONTGOMERY

In determining the percentage loss of moisture at 110 deg. C. it is usual in quantitative analysis to heat the material in question in an ordinary gas oven. Should the material which is being analyzed have any great tendency to hydrate and absorb CO₂, as in the case of portland cement, the loss obtained at 110 deg. C. will very likely be erroneous. The difficulty has been overcome in this laboratory by the use of a small electric furnace through which a stream of dry CO₂-free air is conducted. A cross-section of the furnace, which has been producing satisfactory results for the past three years, is shown in the accompanying diagram. It was designed by Dr. E. O. Harder.

It consists of an iron cylinder 6 in. in diameter and 8 in. long. One end of the cylinder is threaded, and a heavy iron cap, which forms the bottom of the furnace, is tightly screwed to it as shown in the illustration. The furnace is supported by four iron legs screwed into the bottom. The legs are of sufficient length to permit the connection of an air line with the inlet cock and also to provide space for the two electric terminals. Spark

plugs serve as electric terminals. The top or lid consists of an iron cap with a machined groove $\frac{1}{4}$ in. deep and sufficiently wide to permit the walls of the furnace to extend up into the lid as indicated. This arrangement is employed to afford a more closely fitting cover. An iron well through the center of the lid and extending

down into the center of the furnace is half filled with mercury, which affords a bath for the thermometer. A suitable stand of two perforated plates (see sectional plan) with a capacity of sixteen porcelain crucibles rests upon four lugs which are screwed into the wall of the furnace. The plates are attached to each other by means of a central column. This is hollow in order to permit the mercury well to extend down within it. One outlet cock, which serves as an air exit, is provided in the upper portion of the furnace wall. The heating unit consists of 32 ft. of No. 17 nichrome wire in ten coils (these are embedded in fireclay) and secured to an asbestos board. The unit is heated by means of a 110-volt circuit, while external resistance is employed to control the temperature. Compressed air, which is passed through a train of towers containing sulphuric acid, soda-lime and calcium chloride to remove the H_2O and CO_2 , enters the inlet cock at a moderate rate. This furnace is adapted for temperatures up to 250 deg. C. and can easily be controlled within five degrees. The entire furnace is covered with several coatings of heavy asbestos paper.

Structural Materials Research Laboratory,
Chicago, Ill.

Excess Temperature Cut-Out

To prevent the overheating and consequent burning out of heating windings in electric furnaces, a new device has been introduced and provisionally patented by the Automatic & Electric Furnaces, Ltd., the manufacturers of the Wild-Barfield Furnace described in *CHEMICAL & METALLURGICAL ENGINEERING* for Oct. 6, 1920, p. 699. This consists of a replaceable loop of low-resistance wire which enters the furnace for a short

distance connected in series with the heating current. So long as the loop is intact current will heat the furnace. Should, however, the temperature of the furnace, due to neglect, become excessive and so endanger the heating winding, the wire loop melts and interrupts the heating current and at the same time a red pilot lamp or other warning signal is put in operation. A loop having a melting point of 960 deg. C. has been found very useful in protecting furnaces wound with base-metal alloys.

Soda Ash Airveyor

The increasing difficulties in obtaining common labor to unload and handle bulk materials from cars and barges, together with the high cost of wages, are felt all over the country, and this is especially the case where powdery materials, such as cement, soda ash, powdered lime and material of similar nature have to be carried. The injurious effect of the dust makes laborers refuse the work.

The Guarantee Construction Co. of New York, pioneer in the field of building pneumatic conveyors, gave this question considerable thought and study, the result of which was the installation of a portable airveyor at the plant of the Federal Plate Glass Co. in Ottawa, Ill., to handle soda ash, salt cake and powdered lime from cars to bins in an adjacent storage house. Specially designed dust collectors for the purpose have proved very efficient, so that the disposition and loss of dust were overcome in a way entirely satisfactory.

The system used is a suction system, whereby the material is drawn from the car through a flexible hose into a vacuum tank designed to recover a large percentage of the dust floating in the air. This tank, together with a motor-driven positive rotary exhaustor and another special dust collector of the double shell type connected to the exhaust line, is mounted on a movable platform running above the storage bins and

SODA ASH AIRVEYOR

delivers the material through a rotary airlock feeder directly to storage. The dust recovered in both tanks is collected separately and also delivered through rotary feeders to the bins, so that there is very little dust shown at the exhaust.

The airveyor has been in successful operation for about six months, and enables the purchaser to unload material with one man in the car, working under much more agreeable conditions. The inside of car, as well as the storage house, is entirely free from the

obnoxious dust, thus allowing other work to be done on the premises during unloading, which was impossible before.

The airveyor is handling material at the rate of ten tons per hour, and its capacity could have been greater if building conditions had not made it impossible to increase the size of apparatus. Airveyors can be built to handle quantities up to twenty tons per hour for movable units, while when stationary, a capacity of forty tons can be obtained without making the installation too costly and cumbersome.

Electric Arc-Furnace Regulator

High electrode operating speed and close precision of regulation with absolute freedom from hunting are the two important features of the electric arc-furnace regulator just placed upon the market by the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa. Speeds 2½ to 3 ft. per min. depending upon the amount the quantity being regulated is from normal and 5 per cent precision are claimed.

The ability of this regulator to incorporate high speed with a narrow current zone is due to the fact that the electrode speed tapers all the way from full to zero as the regulated current approaches its normal value. In other words, within certain limits the restoring speed is approximately proportional to the amount the current in the electrode deviates from normal. This permits the greatest possible electrode speed for a given current variation. This feature is particularly appreciated during the melt-down of cold scrap. For small variations in current the speed is slow enough to prevent continuous breaking of the arc and at the same time, when the solid metal begins to cave into the pools of molten metal under the electrodes, sufficient speed is available to permit the regulator to extricate the electrode before the time relay allows the breaker to trip. When the current is turned on a furnace charged with cold scrap, it is necessary only to throw the regulator control to the automatic position. Regardless of the position of the electrodes at this time, the regulator will allow each one to run down at full speed until it touches the steel, when complete automatic regulation will commence. It is absolutely impossible for an electrode to get into the steel, and practically no attention is required from the operating personnel.

One very important feature of the regulator is its utilization of the arc voltage as well as the arc current to control the motors. This device absolutely prevents the electrodes getting into the steel under automatic regulation. Under-voltage relay trips on the control circuits are unnecessary. With any purely current actuated device, it is impossible to maintain equal arc

lengths in furnaces using two or more electrodes, particularly when operating at reduced power. In the regulator, the arc voltage, as well as the electrode currents, is maintained balanced.

The voltage coils also make the control of each electrode independent of the others in the surface. In fact, one electrode may be entirely withdrawn without disturbing any of the others. In a regulator dependent upon current control exclusively, any movement of one of the electrodes causes the elements of all other electrodes to change their positions.

Synopsis of Recent Chemical & Metallurgical Literature

Coal-Saving in the Chemical Industry.—A detailed study of the sixty typical steam boiler installations in English chemical plants has been completed recently by DAVID BROWNLIE. The results are given in a series of articles in the *Chemical Trade Journal and Chemical Engineer* (Aug. 21, p. 247; Sept. 4, p. 311; Sept. 11, p. 343). Since these results form part of a comprehensive survey of steam generation methods in British industry as a whole, it is possible to compare the figures for the chemical industry with corresponding data for a group of installations representative of all industries.

The articles cover the methods used in making the tests, a tabulated summary of the results obtained at each of the sixty plants, a detailed discussion and analysis of this table, a summary of the results, and recommendations as to methods for promoting fuel economy in these plants. Since it is almost impossible to summarize adequately a paper of this character, the following excerpts serve merely as an indication of the scope of the article, and the reader is referred to the original for details.

Contrary to what might naturally be expected, the efficiency of steam generation in the chemical plants studied was found to be slightly below the average. In commenting on this, Mr. Brownlie added that he had been struck very forcibly by the lack of organizing and engineering ability displayed in many chemical works. As regards general factory organization and modern methods of costing, many industries such as the motor car trade are so far ahead of the methods generally used in the chemical trade that the comparison is painful. From the point of view of welfare of employees, canteens, lavatories, rest rooms, etc., the chocolate industry and many engineering concerns are in another world compared with most chemical works. As regards engineering, a trained engineer from a steel works, shipbuilding yard or almost any large engineering shop would be considerably staggered at the general engineering of the average chemical plant. Several interesting points will be noted in the detailed analysis of results.

Out of the sixty plants, in only two cases was the fuel analyzed in an accurate manner, so that the quality of the fuel was known. In certainly over 90 per cent of cases the fuel was used without the slightest knowledge of its heating value. As is, of course, well known to steam users today, the fuel supply is so complicated that the consumer is glad to get hold of any kind of coal and there appears to be no control over the quality.

ELECTRIC ARC-FURNACE
REGULATOR

Before the war, however, steam users had a very extensive choice of coal, but in the chemical industry there were certainly not 10 per cent of steam users who analyzed the coal and purchased accordingly.

With regard to scale troubles, there were twenty-seven plants which either had no trouble at all or only slight trouble, twenty-one which might be described as "moderate" and twelve which can only be described as "chronic." It is rather astonishing to find that over 50 per cent of the boiler plants in the chemical industry are in trouble with the feed water, in spite of the fact that in most cases efficient chemists are employed in the plants. The general principle seems to be to leave the boiler plant to the engineering department, which has no time to attend to it, and the interference of the chemist seems to be resented. It is further astonishing to find how many chemical plants buy "quack" boiler compositions and pay exorbitant prices for them.

Of the sixty plants, fifty-five were not equipped with CO₂ recorders and only two plants can be described as fitted with CO₂ recorders in good working order and regularly used. The tests show that the average CO₂ obtained is only about 8.5 per cent. The figures can be divided as shown in Table I.

Only nineteen plants were fitted with superheaters. In these the average temperature of the steam was

TABLE I PER CENT CO₂ IN FLUE GASES

Classification	60 Chemical Plants—		250 Plants Typical of All Industries, Per Cent
	No. of Plants	Per Cent	
Very good, over 12 per cent	4	6.7	1.6
Good, 10 to 12 per cent	14	23.3	6.8
Medium, 8 to 10 per cent	17	28.3	25.6
Poor, 5 to 8 per cent	22	36.7	57.6
Very bad, under 5 per cent	3	5.0	8.4
Total			100.0

340 deg. F. before superheating and 450 deg. F. after—that is, 110 deg. F. superheat. The value of superheating seems to be very little realized. Superheating can be of two kinds. First of all, there is the question of partial superheating (say, 75 to 100 deg. F.), with the idea of completely drying the steam so as to avoid condensation losses in the pipes. Most chemical works have an extensive system of steam pipes, and partial superheating is of particular value in such cases. High superheating (200 deg. F.) is used to increase the efficiency of the steam utilization plant.

The true average net working efficiency for the whole sixty plants was found to be approximately 58 per cent—that is to say, 42 lb. out of every 100 lb. of coal fired

TABLE II EFFICIENCIES OF BOILER PLANTS

Classification	60 Chemical Plants—		250 Plants Typical of All Industries, Per Cent
	No. of Plants	Per Cent	
Over 80 per cent.	0	0	0.8
75 to 80 per cent.	4	6.7	3.6
70 to 75 per cent.	3	5.0	5.2
65 to 70 per cent.	12	20.0	12.0
60 to 65 per cent.	9	15.0	17.6
55 to 60 per cent.	13	21.6	24.8
50 to 55 per cent.	9	15.0	18.8
Less than 50 per cent	10	16.7	17.2
Total	60	100.0	100.0

is wasted. The average is slightly worse than that for all industries (60 per cent). The efficiencies are divided as shown in Table II.

It will be noted that 53.3 per cent of the plants are working with an efficiency of less than 60 per cent and only 11.7 per cent of the plants exceed 70 per cent.

The general conditions of steam generation seem to be much the same all over the world and the average efficiency of boiler plants is probably less than 60 per cent. In the United States the general performance was found to be very poor on investigation by the Fuel Economy Department and opportunities for substantial economies were glaringly evident. An examination by the author of thirty or forty boiler plants in France has shown that although water-tube boilers are in more extensive use and fuel is more expensive and difficult to obtain, it is very doubtful whether the results obtained are any better than in England.

If a boiler plant is considered as a factory in itself, the methods necessary for scientific control are easily visualized. The raw materials are essentially coal, labor, water and air, and the finished product is steam at a given temperature and pressure. Hence, in order to keep an efficient production record, it is necessary to have continuous data on the amount of water evaporated, the amount of steam used in the various processes or departments, the amount of coal burned, the calorific value of the coal and the percentage of CO₂ in the flue gases.

A typical boiler plant of six Lancashire boilers burns 12,000 tons of coal a year, valued at, say, £24,000. The cost of a complete set of instruments, including water meters, automatic coal weighers, CO₂ recorder, coal-testing outfit, pyrometer installation, recording draft- and steam-gages, is less than £1,000. Taking the cost of a skilled attendant at £350 a year, interest at 6 per cent and depreciation at 15 per cent, the total annual expenditure will be about £600. The saving due to efficient control is, on a most conservative estimate, 10 per cent, or £2,400 a year.

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Extracting Metals.—Ores, concentrates, furnace dust and the like, preferably finely divided, are mixed with sodium chloride, preferably in finely divided form or in solution, and the mixture is heated to the volatilization temperature of sodium chloride, whereupon metals are volatilized and may be collected. The process is applicable, for example, to the treatment of lead-zinc ores, lead and silver being volatilized, and to the extraction of other metals such as copper, bismuth and molybdenum. (Br. Pat. 144,728—1919. KRUPP AKT. GES. FÜR GRÜSONWERK, Buckau, Germany, Aug. 11, 1920.)

Frosted Glass.—Relates to a process for producing a mat surface on glass. According to the invention, the glass surface is coated with a composition containing a substance which, when heated, reacts on the glass to form an acid-decomposable product. The composition also contains a relatively inert substance and a binding agent. The coated surface is heated to the required extent and, after cooling, the acid-decomposable matter is removed by an acid other than hydrofluoric. As an example, a composition consisting of basic lead silicate,

pulverized porcelain and a binder such as gum is described. (Br. Pat. 144,737—1919. T. UEDA, Kyoto, Japan, Aug. 11, 1920.)

Electric Endosmose.—Before separation by electric endosmose of mixtures of colloids, ions and non-ionized bodies, ions which are unsuitable for the process are replaced by more suitable ones—for instance, chloride, sulphate, or phosphate ions by inorganic or organic ions of the same or different valency, or calcium, magnesium or aluminum by ammonium, sodium, or potassium. If a mixture containing ammonium sulphate and albumin is treated in a three-compartment cell, even the most electro-positive diaphragms do not prevent more rapid migration of the ammonium ions and consequent acidity of the mixture in the middle compartment; but after treatment of the mixture with barium acetate and removal of barium sulphate, the mixture on electrolysis with a positive diaphragm at the anode remains feebly alkaline and albumin is not precipitated. If barium chloride is similarly used, the mixture keeps feebly acid. Both anions and cations can be replaced; for instance, if aluminum sulphate is present, the aluminum can be replaced by ammonium and the sulphate ion by a monovalent one. (Br. Pat. 144,710—1919. ELEKTRO-OSMOSE AKT. GES., Berlin, Aug. 11, 1920.)

Organic Metallic Compounds, Arsine Derivatives.—Amides and acids of the general formulæ $R_3AsCONH_2$ and $R_3AsCOOH$, when R = a fatty or aromatic radical, are prepared by hydrolysis of the corresponding nitriles R_3AsCN . According to examples, dimethylarsinoformic acid and diphenylarsinoformic acid are obtained by treating cacodyl nitrile and diphenylarsine nitrile with dilute sulphuric acid; diphenylarsine nitrile is converted into the corresponding amide by hydrogen peroxide, and the amide converted into diphenylarsinoformic acid by sodium nitrite and sulphuric acid. Dimethylarsinoformic acid forms salts with sodium, calcium, magnesium, manganese, iron, cerium, mercury, quinine, strychnine, etc. (Br. Pat. 144,806—1919. A. JOB and H. GUINOT, Paris, Aug. 18, 1920.)

Lecithin.—Lecithin is separated from animal or vegetable matter containing it, or from crude lecithin, by dissolving the raw material—e.g., egg yolk or fish roe—in an organic solvent, treating the solution with hydrogen in the presence of a hydrogenating catalyst such as palladium or nickel, interrupting the hydrogenation when the lecithin has been saturated, as shown by test extraction with cold ethyl acetate, then evaporating off the solvent, and dissolving the residue in hot ethyl acetate, from which, on cooling, the lecithin separates out. (Br. Pat. 144,895—1919. C. BAUMANN and J. GROSSFELD, Recklinghausen, Aug. 18, 1920.)

Cuprammonia Cellulose Solutions; Artificial Threads.—Solutions of cuprammonia cellulose, which are permanent and capable of being satisfactorily spun, are obtained by the addition of sugars both of the grape-sugar group and of the cane-sugar group; the former are added to prevent oxidation of the cupric salt and of the cellulose, and an amount of 0.25 per cent of the cellulose taken is sufficient; the sugars of the cane sugar group and of which refined beet sugar is the most suitable, are added to effect or maintain the hydration of the cellulose, and of these sugars it is sufficient to add 2 per cent of the weight of cellulose taken, or a little more if the cellulose has not been decomposed. By the addition of a reducing sugar, it is stated that the solubility of cupric oxide in ammonia is increased, and the

solution of the cellulose in such solution rendered more rapid and complete. (Br. Pat. 145,035—1919. GLANZFARBEN AKT. GES., Petersdorf, Germany, Aug. 18, 1920.)

Dental Cements.—Colloidal silicic acid in the form of hydrogel, acetogel or alcogel, is added to dental cements of the kind in which a phosphoric acid or acid phosphate is an ingredient to prevent the liberation of acid after the cement has set. The silicic acid may be added to the powder before it is mixed with the phosphoric acid, or the powder may be mixed with a solution of the silicic acid in phosphoric acid or an acid phosphate. In an example, to a solution of magnesium and aluminum sulphates in molecular proportions is added sodium silicate and caustic soda lye until the magnesium aluminum silicate is precipitated. Colloidal silicic acid is added and the precipitate is filtered, dried and mixed with phosphoric acid and an acid phosphate. (Br. Pat. 145,052—1919. S. SCHIFF, Karlsruhe, Aug. 18, 1920.)

Preparation of Urea.—Urea is prepared by forcing a mixture of carbon dioxide and ammonia into an autoclave and maintaining the melt formed for a sufficient time at the temperature required for the transformation of ammonium carbamate into urea. The process may be carried out in a continuous manner by forcing the gases into an autoclave and keeping the melt at 135 deg. C. for two hours, then slowly releasing the reaction mass through a bottom valve to a column still in which it is distilled, urea solution running off from the bottom of the still while unchanged ammonia and carbon dioxide pass off to a dephlegmator and thence back to the compressor. More ammonia and carbon dioxide are supplied to the autoclave, or an aqueous solution of ammonium carbamate or carbonate is supplied to the top of the column still. The amount of moisture in the gases led back to the compressor may be controlled by keeping the temperature at the outlet of the dephlegmator at say 60 deg. C. The expansion of the melt may be allowed to take place in two stages to save compression energy. (Br. Pat. 145,060—1919. BADISCHE ANILIN UND SODA-FABRIK, Ludwigshafen-on-Rhine, Aug. 18, 1920.)

Separating Suspended Impurities From Gases.—In the electrical separation of impurities suspended in gases, there is employed an undamped pulsating unidirectional voltage having a frequency considerably higher than about 50—the frequency ordinarily employed with alternating current—and preferably having a medium frequency of the order of 250-1,500 periods; a frequency of 500 is particularly advantageous. It is stated that such a pulsating voltage may be superimposed on “a constant direct-current voltage pulsating with low frequency.” (Br. Pat. 145,477—1919. METALLBANK UND METALLURGISCHE GES., Frankfurt-on-Main, and J. E. LILIENFELD, Leipzig, Sept. 1, 1920.)

Deodorizing Soap.—Liquid soap is deodorized by treating it under pressure—e.g., in an autoclave at a temperature above 100 deg. C. with steam. The autoclave may be heated by direct firing or by admission of superheated steam. Hot water or steam, as the case may be, is admitted so as to keep the concentration of the soap solution approximately the same during the operation. After some hours a valve in the autoclave is opened, and odoriferous impurities are carried off by the escaping steam. (Br. Pat. 145,502—1919. PERSAPOL GES., Hanover, Germany, Sept. 1, 1920.)

Current Events

in the Chemical and Metallurgical Industries

Conservation of Timber by Chemical Treatment

On Friday evening, Nov. 5, the American Section of the Society of Chemical Industry met at the Chemists' Club for a conference on conservation of timber by chemical treatment. Sumner R. Church presided. Herman von Schrenk spoke on the preservative treatment of wood and forest resource conservation. About 65,000,000 gal. of creosote oil is used annually at present. The supply can be increased greatly if the practice of burning the crude coal tar at the coke and steel plants ceases. About 43,000,000 lb. of zinc chloride, the second most important preservative, was consumed last year and ample supplies are available to meet any demand. Mercury and fluoride salts are exceptionally good for these purposes, but comparatively are too costly. Interesting and instructive slides were displayed showing graphically the amount of timber available, and the excess of consumption over production. Mr. von Schrenk drew conclusions showing how preserving would assist in overcoming this discrepancy between consumption and production.

Mr. Kuehn spoke on the outlay and operation of a modern wood preserving plant. He discussed very fully the methods of treating wood in the preserving plants. There are in the United States 132 such plants. The output of these plants has been only 160,000,000 cu.ft. of wood, a very small percentage of the wood utilized. Mr. Kuehn said that the development of the industry was being held back by the shortage of coal tar and other preserving chemicals. He discussed fully the most approved methods of handling the wood and piling it in the storage yards. He called attention to the necessity for proper seasoning of the material before treatment and he also gave a thorough explanation of the methods of treatment, calling particular attention to the difficulties encountered and the means by which they were overcome. His talk was fully illustrated with slides showing the various processes in actual operation.

At the close of the meeting a buffet lunch was served in the rooms of the Chemists' Club. About two hundred members and guests of the society were present at the session. Suggestions for topics for forthcoming meetings were asked by the directors, who are making every effort to make the sessions both interesting and instructive to the members.

Consulting Chemists Named for C.W.S.

To form the nucleus for his consulting staff General Amos A. Fries, the Chief of the Chemical Warfare Service, has designated each member of his advisory committee a consulting chemist of the bureau. The chemists thus designated are W. D. Bancroft, R. C. Tolman, A. B. Lamb, E. P. Kohler, F. M. Dorsey, W. K. Lewis, L. T. Sutherland, L. C. Jones, C. L. Reese, William H. Walker, Bradley Dewey, Reid Hunt, A. S. Loevenhart and Julius Stieglitz.

The advisory committee has been asked by General Fries to designate other chemists who may be induced to assist the bureau in a consulting capacity.

Composition of Automobile Exhaust Gases

A. C. Fieldner, speaking before the Chemical Society of Washington on Oct. 28, reported an extensive series of investigations made by the Bureau of Mines on the composition of automobile gases in relation to ventilation of vehicular tunnels. This work has demonstrated a number of important conclusions as to the extent of incomplete combustion in automobile engines. An average of about 6.4 per cent carbon monoxide in the exhaust gases from all types of machines tested for all conditions of test is reported. With the proposed vehicle tunnel from Manhattan to New Jersey this represents at the full capacity of the tunnel a discharge of about 400 cu.ft. of carbon monoxide per minute, which would require for proper elimination the movement of approximately 1,000,000 cu.ft. of air per minute.

The percentage of carbon monoxide in the exhaust varies widely with the adjustment of the carburetor and the conditions of driving. The largest percentages of carbon monoxide are formed when accelerating or climbing grades—that is, at the time of greatest power demand. The point of maximum power production from an engine is quite different from the point of maximum thermal efficiency. At the point of maximum power richer mixture is used than corresponds either to the point of maximum thermal efficiency or to the point of theoretical air-gasoline ratio. As a practical matter, the best remedy for gasoline losses caused by inefficient operation is, in the opinion of Dr. Fieldner, to be accomplished only through more extensive use of dash control devices so that the richness of the mixture can be adjusted by the driver according to the power demands.

To Get More Data on Gas Wounds

In order that all available information on gas casualties in the American Expeditionary Forces may be compiled, the Surgeon General of the Army is having all information with regard to such casualties segregated from the records. One of the significant developments of the war is the fact that gas caused a large percentage of the casualties, comparatively few of which resulted fatally. It is claimed that no single case of tuberculosis can be traced directly to injury from gas. One of the the objects of the present inquiry is to verify this assertion.

New Haven Section of A.C.S. and Bridgeport Chapter of A.S.M.E. Hold Joint Meeting

The New Haven Section of the A.C.S. and the Bridgeport Chapter of the A.S.M.E. held a joint meeting at the Seaside Club in Bridgeport, Friday evening, Oct. 19, 1920.

John R. McGregor of the Eagle-Picher Lead Co. gave a very interesting and instructive lecture, illustrated by moving pictures, on the prospecting, mining and smelting of lead ore and the manufacture of lead products from pig lead, which was enjoyed by all present.

Future of International Catalog of Scientific Literature Considered at London Conference

An international conference of delegates from important scientific academies to consider the future of the International Catalog of Scientific Literature has just been held in London at the invitation of the Royal Society. Representatives were present from fourteen countries. The American delegates were Dr. R. M. Yerkes, Prof. L. E. Dickson, Prof. L. P. Eisenhart, G. C. Gunnell and Dr. S. I. Franz, representing the National Academy of Sciences, the National Research Council and the Smithsonian Institution.

Up to the time of the war, more than thirty countries were joined in undertaking the indexing and publishing the index of the scientific literature of the world. Fourteen annual issues, each of seventeen volumes, have been published covering the literature from 1901 to 1914. The results of the war, together with the much increased cost of printing and publishing, have interrupted the undertaking and no index of scientific literature published since 1914 has been issued. The conference decided that even though a change may be made in the future in the method of indexing and of publishing the index, as has often been suggested, it is imperatively necessary to continue the present method until the scientific literature published up to the end of 1915 and possibly also that up to the end of 1920 has been catalogued.

Business Conditions of Ohio Chemical Industries

In a majority of the industries of Ohio production is at a low ebb. Manufacturers feel that they are facing a period of readjustment and a move toward lower price levels. There is no feeling of pessimism in the reports emanating from the various centers—in fact, operators feel confident of a stimulated demand with a return to a more normal basis.

In the Akron district the production of tires and other rubber products is at its lowest point and manufacturers are taking advantage of the situation to conduct inventories. On Nov. 1 the Goodyear Tire & Rubber Co. resumed operations on a four-day weekly basis with daily production at about 6,000 tires. The Firestone factories are operating on a five-day weekly basis. The outlook for the tire industry is not of the best. Most of the larger companies are operating on a 20 to 25 per cent of normal production basis.

Annual inventories showed that the larger companies were hard hit by high prices on raw material. Accustomed to buying in the open market in large quantities, they are reported to have large stocks of raw rubber and cotton which were purchased at the peak of high prices. Now that prices on both have dropped considerably, it is only the smaller companies that can take advantage of present prices, having bought on a closer margin.

On the other hand the paper mills of the Miami Valley district report much better conditions. During the past few weeks they have been able to maintain maximum production through firmer supplies of pulp and fuel. Few of them, however, have a reserve supply, but no curtailment is expected because of shortage of raw material in the immediate future.

The Champion Coated Paper Co. has let contracts for a new building 720 x 55 ft. to house the sizing and bleaching departments and to provide additional clay storage space. Work will be started about Dec. 1.

Iron and steel operators in the Youngstown district report slightly reduced production. The inflow of new business is not up to the rate of shipments, which means, of course, slowing up of operations unless buying revives shortly. There is a general feeling in this district that the industry will encounter readjustments and move toward a lower price level before the big overhanging demand for steel makes itself fully felt. There is no evident indication to be pessimistic over the outlook, but rather a feeling of relief among the leading producers that a return to more normal conditions is in sight. Opinion among local bankers and business men is that the district is in an exceptionally comfortable position for any readjustments that may come.

The fuel situation is acute in the East Liverpool pottery district. Most of the potteries are from six months to a year behind in production and no promises are being made for future deliveries. The transportation situation is especially acute and little coal is being received. Because of gas shortage many of the potteries are substituting fuel oil for kiln firing as the most feasible solution of the fuel problem.

Bureau of Mines to Push Co-operative Work

During the next few months L. I. Shaw, the Assistant Chief Chemist of the Bureau of Mines, will be attached to the Columbus Experiment Station of the bureau to conduct intensive work looking to the formation of co-operative agreements with ceramic industries.

The Bureau of Mines now has in effect with state institutions and private companies co-operative agreements which make available more than half a million dollars annually as a supplement to the Congressional appropriations allowed the bureau. One of the conditions of these co-operative agreements is that the results of these experiments are to be made public so that the entire industry may have the benefit of the work. Due to the success which has attended this form of activity on the part of the bureau it is expected that considerable expansion of this activity will take place in the future.

General Staff May Be Ousted

One of the probable effects of the change in the national administration will be the appointment of a new Chief of the General Staff of the Army. The present Chief of Staff opposed the continuance of Chemical Warfare Service and is believed to regard the development of military gases as a matter of small importance. Despite the very decided manner in which Congress overruled the recommendation of the General Staff in regard to chemical warfare there are evidences that the new service has not been accorded the same sympathetic consideration as have certain of the older branches. There is a feeling among chemists that the Chemical Warfare Service will fare much better under nearly any officer likely to be appointed Chief of Staff.

Portland a Distributing Center for Sulphur

Portland, Ore., is gaining increasing prominence as a distributing point for sulphur. Shipments totaling about 10,000 tons of this mineral have recently been landed at Portland by steamers from Galveston and Sabine, Tex. Much of the sulphur is used by the paper mills in the neighboring towns of Oregon City and West Lynn, Ore., and Camas, Wash.

Imports and Exports of Chemicals

Heavy increases in chemical imports took place in September as indicated by the figures which just have been assembled by the Bureau of Foreign and Domestic Commerce. The imports of chemicals on the free list are at a rate double that of last year, as shown by the figures for the first nine months of 1920. During September of 1920 the importations of duty free chemicals aggregated \$13,229,907. This compares with \$7,054,012 in September of 1919. The imports of dutiable chemicals decreased in September of this year as compared with the corresponding month of last year.

Fertilizers during the first nine months of the current year are being imported at about eight times the rate of importation during the corresponding period of last year. During September, just past, fertilizers to the value of \$4,195,848 were imported. In September of 1919 the value of the imports was \$890,097. Imports of coal-tar products increased from \$512,004 in September, 1919, to \$870,057 in September, 1920. Potash imports in September, 1919, were valued at \$25,200. This year in September \$445,083 worth was imported. Comparative figures as to the importation of certain chemicals which come in in smaller volume, are as follows:

	September 1919	1920
Ammonia, muriate of	\$40,395	\$38,930
Arsenic, sulphide of	36,043	33,813
Glycerine, crude	50,882	160,866
Iodine	2,275	7,972

Exports of chemicals in 1920 ran a million dollars higher than they did in September of 1919. Acid exports increased from \$425,160 in September of 1919 to \$483,043 in September, 1920. Dye exports increased from \$1,425,983 in September, 1919, to \$3,119,295 in September of 1920. Our exports of dyestuffs to China have tripled. The United Kingdom is buying much more heavily in the American dye market. Mexico's increased buying power is reflected in its greater purchases of American dyes. India and nearly all the South American countries took American dyes during September. The total soda exports in September of 1919 were valued at \$1,845,715. The exports in September of this year were valued at \$2,131,347. Some of the chemicals exported in lesser amounts are as follows:

	September 1919	1920
Formaldehyde	\$155,833	\$302,150
Chlorate of potash	36,407	28,229
Chloride of lime	47,636	180,719
Sulphur	763,346	700,841
Petroleum jelly	213,806	205,281

World Trade Club Formed in St. Louis

The recent organization of the World Trade Club of St. Louis, with over 100 members, by the Foreign-Trade Bureau of the Chamber of Commerce, the local representative of the United States Bureau of Foreign and Domestic Commerce and export managers representing the largest exporting industries is another indication of the interest being taken in foreign trade by manufacturers located in the interior cities.

The object of the club will be the promotion of foreign-trade interests of the city of St. Louis and the Mississippi Valley. It will work along the same line as the Export Managers' Club of New York, the Exporters' Round Table of Boston and the foreign-trade clubs of Chicago and San Francisco. Regular meetings will be held in the form of a round-table discussion in order

that export managers may have an opportunity to discuss their problems and secure practical advice and assistance from members who have had experience along similar lines. From time to time authorities on certain phases of export trade will be brought to St. Louis to give the local men the benefit of their studies and experience.

The largest exporting firms and the various foreign-trade promotive agencies are represented on the executive committee in order to co-ordinate in one organization all industries and associations active in foreign trade. The officers of the club are: President, F. Ernest Cramer; vice presidents, R. P. Block, W. E. Tarlton and A. H. Boette; secretary and treasurer, J. A. Troy.

New Motor Fuel in South Africa

In addition to natalite, which is manufactured in Natal from the refuse of the sugar-cane mills and used extensively in propelling motor cars in South Africa, there has recently been produced another motor fuel to meet the shortage and high cost of gasoline in that country, reports Vice-Consul Pizar of Cape Town. The basis of this new fuel, which is called "acetol," is alcohol and ether, which comprises 90 per cent. The other ingredients are treated as a secret until the patentee receives his patent rights.

It is said that this fuel apparently solves the question of the air-cooled engine. No carbon sediment is formed in the cylinder, and the fuel is claimed to be non-injurious to the carburetor and engine. No special carburetor is required. Acetol mixes with gasoline. The inventor claims that it has a wider explosive range than the ordinary marketed gasoline—i.e., both a weaker and an over-rich charge in the cylinder heads will fire when gasoline fritters out or chokes. Tests made with this fuel are said to have produced very satisfactory results.

It is claimed that acetol can be manufactured much more cheaply than the present cost of gasoline in South Africa. The retail selling price of gasoline at the coast ports of that country, which is fixed by the government, is \$1.12 per imperial gallon (1½ American gallons) if purchased in cases of two cans containing 4 gal. each, and \$1.22 per gal. if purchased in smaller quantities. Natalite now sells for 60c. per gal.

Non-Metal Industries Looking Up

After a visit to the principal centers of production of non-metals in the Mississippi Valley, R. P. Ladoo of the Bureau of Mines has returned to Washington with the report that a new spirit seems to characterize this industry. Businesslike methods are being adopted by even the smallest operators. Waste is being eliminated and economies of various natures are being adopted. In many cases the most improved machinery is being installed.

The most important single activity seems to be in bauxite production. In that industry there is a decided tendency to undertake large preliminary expense so as to achieve ultimate economies and maximum production. The labor shortage is being met by the employment of Mexicans, who are reported to be giving entire satisfaction.

The market for tripoli is widening, with the result that greater activity is being manifested in its mining and treatment. The success with which the flour of this material is being used as a filler for rubber and in

foundries as a parting for molds has added importantly to the demand.

While some of the smaller fluorspar operations are closed, all of the large companies are operating at a maximum capacity. Mr. Ladoo believes this to be largely because the more highly organized companies produce a more uniform grade of product. An indication of the promising outlook for that industry is the recent decision to erect a \$1,000,000 mill on the Rosiclare vein in southern Illinois. Mr. Ladoo also found the flint clay and diaspore industries enjoying general prosperity.

New Italian Process for the Manufacture of Synthetic Ammonia

In the manufacture of synthetic ammonia by the Haber process the great difficulty encountered is that the catalyzers soon become poisoned. The correction of this difficulty constitutes the essence of the new Italian process for producing synthetic ammonia. After long experimentation, a catalyzer has been found which continues to function despite any impurities in the hydrogen and nitrogen gases. Further, an extremely simple apparatus for its employment has been developed. Nature herself may be said to employ a species of catalytic process in rendering atmospheric nitrogen available to the soil. Certain leguminous plants, as cow-peas and clovers, appropriate atmospheric nitrogen and store it up in their root nodules, transferring it thence to the soil.

In the synthesizing plant at Terni, about sixty miles north of Rome, the only raw materials used are the air and water. With a limited equipment it produces about 300 kilos (kilo — 2.2 lb.) of ammonia per day. Water power in abundance is furnished by the adjacent falls at Terni. The energy of the falling water is converted into electricity and the water, in turn, is acted upon by the electric current to produce hydrogen. This gas is then piped to the apparatus which extracts nitrogen from the air. Being a trade secret, the process of this extraction cannot be explained fully. It is carried on in a large steel cylinder resembling the upright boiler of a 50-hp. double-drum, stationary hoisting engine. The apparatus works automatically, running for days without attention. The nitrogen-hydrogen mixture is led from the boiler-like receptacle, heated, and passed under low pressure into a tube-like cylinder, where it is conducted through the catalytic substance. Here the desired combination takes place. The ammonia thus produced is condensed into liquid form by a refrigerating apparatus and drawn off from time to time in steel cylinders. It is put on the market in these cylinders at prices which are said to be at least 100 per cent above the cost of production. The whole apparatus, aside from the cells for producing the hydrogen, easily can be made to occupy a space of about 625 sq.ft. Just now the plant is undergoing enlargement, its capacity by Dec. 1 to be at least 1,000 kilos of pure ammonia per day.

Dr. Casale, the Italian inventor of the process, has gone even further in his work of synthesizing ammonia, having practically completed a process of utilizing this product in the manufacture of urea. This substance, by reason of its high nitrogen content of 45 per cent and carbon dioxide remainder, is a most valuable source of soil fertilizer and is chemically classed with that ancient restorer, barnyard manure.

The development of this new Italian process from a purely theoretical to a commercially fruitful status has

been made possible through the interest and financial backing of an American capitalist. Some time ago this American secured a concession from the Italian Government for water-power rights at Terni, and is now negotiating for other concessions which will enable him to duplicate the Terni facilities.

Industrial Nurses Convene at New Haven

A convention of industrial nurses, the first of its kind, was held this fall at the New Haven School for Public Health Nursing. Fifty-four registered public health nurses from eight states attended. The varied industries represented and the discussions of the nurses brought out very clearly the fact that, while no fixed rules can be worked out to fit all places, it is possible to state definitely the fundamental principles of industrial nursing.

There were representatives from a university mercantile department, a state department of health, visiting nurse associations; canning, packing, chocolate and soap industries; woolen and cotton mills; brass and iron foundries; wire and paper mills; manufacturers of leather and rubber goods; monument, typewriter and corset works; roller bearings, sporting goods, tools and electrical appliances; printing and oil plants. The states represented were Connecticut, Massachusetts, New York, Rhode Island, New Jersey, New Hampshire, Illinois and Michigan.

The program lasted ten days and included lectures and round tables on Public Health Nursing, Industrial Nursing, Industrial Hygiene, Industrial Diseases, Records, Ethics of Industrial Nursing and Medicine, Industrial Relations, Social Problems, Industrial Psychology, Nutrition, Health Education, as well as excursions to manufacturing plants. Four periods were given over to lectures on recreation and other methods for counter-acting industrial monotony. Play demonstrations were given and every one joined in folk dancing and simple games.

Book Reviews

MANUAL OF CYANIDATION. By E. M. Hamilton. 278 pages, illustrated. New York: McGraw-Hill Book Co. Price \$3.

In this excellent little text of 253 reading pages Mr. Hamilton presents in very readable form and with little surplus verbiage the essential features of the cyanide process as now practiced. The book is written in a suggestive style, with many definite references to original sources, and should prove useful to those practically engaged in cyanidation, and also as a textbook for technical schools giving instruction in the metallurgy of gold and silver. The typographical work is good, the book of convenient pocket size and well bound in flexible cloth, an improvement over the flexible leather of a few years ago.

The chemistry of cyaniding is presented in Chapter I, and the control of operations by testing of various kinds in Chapters II and III, the former dealing with the tests required on solutions, and the latter with general testing of ores as to their suitability for treatment by cyaniding, and best conditions of treatment. The chief methods of employing the process are then taken up under the headings of "Sand Leaching," "Slime Treatment" and "Milling in Cyanide Solution." These chapters constitute a very satisfactory description of the ordinary apparatus and principles and conduct of the several processes. The causes of

discrepancies between actual recovery and theoretical extraction are discussed in Chapters VI, VII and VIII with a view to their relative seriousness and control. Telluride and other ores presenting special difficulties are discussed in a separate chapter. The recovery of gold and silver from solutions is covered in Chapter I on "Precipitation" and Chapter II on "Cleaning Up and Melting." In the last two chapters are given representative plant costs and data and a considerable number of tables of miscellaneous information, the data in both chapters being well chosen for their practical value and suggestiveness. S. L. GOODALE

* * *

HANDBOOK OF ORE DRESSING. By A. W. Allen. 242 pages, illustrated. New York: McGraw-Hill Book Co. Price \$3.

In this book Mr. Allen has brought together a great deal of information and presented it in small compass and easily accessible form. There are 230 pages of reading matter, tables and illustrations, and a short bibliography. The book is of pocket size, well bound in flexible cloth, and the presswork is good, the type even in the tables large enough to be easily read. Most of the data are presented in tabular or diagrammatic form with directions for use of the tables and diagrams. There are a large number of excellent cuts of machinery and apparatus, with short description accompanying each, but not going into minute detail. Comparative data as to machines and processes are frequently presented and should prove of real value. The theoretical matter of interest in ore dressing is taken up as fully as the space of the volume permits, and it seems that the book should find much use in the libraries of all engineers who handle ore-dressing problems. S. L. GOODALE.

* * *

LABORATORY MANUAL OF ELEMENTARY COLLOID CHEMISTRY. By Emil Hatschek. Philadelphia: P. Blakiston's Son & Co., 1920. 133 pp., with 20 illustrations. Price \$2 net.

In this welcome little manual there are compressed a large number of practical exercises in colloid chemistry, involving simple and inexpensive apparatus and modified by the author's teaching experience. "—the guiding principle has been to provide for the wants of those students of numerous branches of science who are finding some training in colloid chemistry an indispensable part of their equipment, and are able to devote a limited time only to acquiring its technique. For the guidance of readers desirous of going beyond the limits of this manual a number of references to recent literature are given at the end of each section."

The chapters are: General remarks on apparatus, materials and procedure; dialysis; suspensoid sols; suspensions; organosols; emulsoid sols and gels; egg albumin sol; emulsions; ultra-filtration; optical methods of examination; cataphoresis; electrolyte precipitation of suspensoid sols; mutual precipitation of suspensoid sols; protection; viscosity measurements; absorption (qualitative experiments); capillary analysis; determination of an adsorption isotherm; the Liesegang phenomenon.

There are many bits of simple but necessary advice such as to avoid pouring a viscous sol into a thin solvent during dilution; for although common sense and "kitchen experience" should indicate the reverse order, the beginner is apt to proceed hastily and get into trouble.

The instructions are for the most part very clearly and concisely given. But on p. 32 the author says regarding the preparation of colloidal silver by Carey Lea's method: "The color of the sol, and in fact the success of the whole method, depends a good deal on the quality of the dextrine, which can be determined only by experiment." It seems to the reviewer that it should be easy to give specifications for the quality and kind of dextrine best suited for this purpose.

The author adheres to Wo. Ostwald's classification of colloids into "suspensoids" and "emulsoids," but Zsigmondy's classification into "reversible" and "irreversible" colloids seems more desirable. Thus on p. 35 (footnote) the author says regarding ferric hydroxide sol: "Although this sol has some emulsoid properties, it is classed here with the

suspensoids on account of its behavior to electrolytes, etc." On p. 41 some specification should be given as to the kind of commercial waterglass to be used, for the commercial grades vary widely in their ratio of SiO_2 to Na_2O . It is interesting to note that ammonium thiocyanate exercises marked protective action on colloidal SiO_2 . A very simple optical method for determining the setting point of gelatine solution is based on the fact that during the last stage of setting the surface of the sol forms a network of wrinkles (which are not due to drying). On p. 64 reference is made to Stokes' formula, but the formula is not given, as it should be, to save the student the trouble of looking it up. The size of the chapter on "protection" is not commensurate with the importance of the phenomenon.

Regarding Liesegang's rings, it is stated: "To produce really good rings the gelatine must contain a small amount of acid and of gelatose (a product of hydrolysis which does not gelatinize on cooling)." This would indicate that the reaction takes place in the diffusion paths formed by the dispersion medium, where the protective action of the gelatose should be a factor.

The book fills a want not only because of its intrinsic merit, but also because it is the first of its type.

JEROME ALEXANDER.

Personal

A. W. AMBROSE will become chief petroleum technologist of the Bureau of Mines on Nov. 15. He succeeds J. O. Lewis, who has resigned to enter private employment. Mr. Ambrose is a native of California and is a graduate of the College of Mining at Stanford University. He spent a number of years on work dealing with the relation of geology to drilling and production in the California, Texas and Louisiana oil fields. He has been with the Bureau of Mines since 1917. Since Feb. 1 he has been superintendent of the bureau's petroleum station at Bartlesville, Okla.

C. W. BATES has recently accepted a position in the engineering department of the Anaconda Lead Products Co., East Chicago, Ind.

WARREN F. BLEECKER, metallurgical engineer, of Boulder, Col., was in New York last week on a business and professional trip.

General Sir ARTHUR CURRIE, former commander-in-chief of the Canadian army in France and now principal of McGill University, Montreal, visited Chicago recently and was entertained at luncheon by David R. Forgan. He later addressed a joint meeting of the Canadian Club and McGill Alumni at the Morrison Hotel, and outlined McGill University's need of additional funds to make up for losses during the war. A campaign will be launched on Nov. 15 for \$5,000,000, to include building equipment for the university and living wages for McGill's faculty.

Dr. F. L. DEBEUKELAER, who received his Ph.D. degree from the University of Chicago last summer, is now employed as research chemist in the glue and gelatine department of Swift & Co., Chicago, Ill.

GORDON FOX, formerly with the Fort Wayne works of the General Electric Co. and lately electrical engineer of the Mark plant of the Steel & Tube Co. of America, has joined the staff of Freyn, Brassert & Co., engineers, Chicago, Ill., in the capacity of electrical engineer. Mr. Fox is chairman of the Chicago Section of the Association of Iron and Steel Electrical Engineers.

LOUIS D. HUNTOON and G. D. VAN ARSDALE have formed a partnership under the name of Huntoon & Van Arsdale, and will engage in consulting engineering in mining, metallurgy and geology. As previously announced, Mr. Van Arsdale will be in Los Angeles, while Mr. Huntoon will remain in New York City.

I. O. JUVRUD has been appointed chief chemist for the Portland Flouring Mills Co. of Portland, Ore. His former

work in this line has been with the Kansas Milling Co. of Wichita, Kan., and the Atkinson Milling Co. of Minneapolis.

HARLAN S. MINER of the Welsbach Co. addressed the Eastern Section of the American Chemical Society at Union College, Schenectady, N. Y., on Nov. 5, on the subject of "Thorium, Mesothorium, Cerium and Other Rare Earths."

ABRAHAM A. ORLINGER, holder of the New York Chemists' Club Hoffman scholarship for 1919-20, has been awarded the scholarship for 1920-21. Mr. Orlinger is completing the chemical engineering course at the Massachusetts Institute of Technology.

D. L. SCOLLES, who has been at the Iowa State College at Ames, Iowa, for five years, has resigned as assistant professor of chemistry to accept a position as head of the department of chemistry at Illinois Wesleyan University, Bloomington, Ill.

Dr. LEE IRVIN SMITH, who was formerly an instructor in chemistry at Harvard University, is now instructor in organic chemistry, University of Minnesota, Minneapolis, Minn.

NEWTON W. SPEECE, who served two and one-half years during the year as a Captain of infantry, with over a year's service in France, is now instructor of chemistry at the University of Minnesota, Minneapolis, Minn. Mr. Speece is a graduate and post-graduate of Dickinson College, Carlisle, Pa.

R. B. STRINGFIELD, formerly superintendent of the chemical department of the Pacific Minerals & Chemical Co. and chemical engineer with the Arthur R. Maas Laboratories of Los Angeles, has accepted a position as chemical engineer with the Goodyear Tire & Rubber Co. of California, Los Angeles.

Current Market Reports

The Iron and Steel Market

Pittsburgh, Pa., Nov. 5, 1920.

Pig iron production in October was at a slightly lower rate than in September by the merchant furnaces, but at a materially greater rate by the steel works furnaces, so that on the whole there was a slight increase. Many furnaces blew out late in October, however, so that the rate at the close of the month was well below the average rate in September. In the rate of steel ingot production there was probably a decrease from September to October, taking the months entire, while the rate now is well below the October average, being probably between 10 and 15 per cent below the rate of 42,700,000 tons per annum in ingots shown for both September and August.

The Steel Corporation's output has not decreased, but if anything has increased. One or two large independents seem to be operating at as heavy a rate as formerly, but nearly all independents are at reduced rates. In some cases the reductions are small, in other cases large. Not a few plants are operating at less than 60 per cent. In all cases it is a matter of order books. The volume of business on books is in inverse ratio to the prices charged. Independents that were relatively conservative in the matter of prices have such order books that, despite cancellations and postponements, they can operate at fair rates, say above 75 per cent. Others, with lean order books, must be contented with lower rates, even though they seek new business at cut prices. There is not much business to be drawn out by cutting prices, and the cuts proceed by easy stages.

In not one case thus far is an independent selling any steel product at the Steel Corporation or Industrial Board price. The expectation is practically universal that the independent market will decline to the Steel Corporation level, and the whole market will then be equalized, except

for such cutting as some independents may be forced to indulge in so as to regain lost customers. The chief question debated is how long the process of equalization will require. Some say by January, some by April, the readjustment will be completed.

A possible objection to the prediction is that it is so universal. Some say "majorities are always wrong." On the other hand, it may be urged that if a buying movement occurs in steel after a period of dullness it takes care of itself, the buying producing a stiffening in the market, and the stiffening producing additional buying. It is said that what is needed is "confidence," and if every one expects the steel market to decline to the Steel Corporation level and then stop, certainly there should be confidence in the market when it gets to that point.

STEEL PRICES

There are no longer any delivery premiums, except as it may be said that independent prices represent delivery premiums on account of their being above Steel Corporation prices, with the Steel Corporation very well sold up. Purchases are not being made from independents for extended deliveries, so that the prompt market is all there is in the independent market. Prices are roughly as follows, the Steel Corporation price being named first and the independent price next: Bars, 2.35c. and 3c.; shapes, 2.45c. and 2.90c. or 3c.; plates, 2.65c. and 3c.; nails, \$3.25 and \$4.25; standard steel pipe, 57½ and 54 per cent off list; blue annealed sheets, 3.55c. and 5c.; black sheets, 4.35c. and 6.25c.; galvanized sheets, 5.70c. and 7.75c.; tin plate, \$7 and \$8.50. In the case of sheets and tin plate the corporation is not a seller, but it will open its books next month for first half contracts with regular customers, to be filled after the carried-over business is completed, this requiring approximately the first three months of the new year.

PIG IRON

Pig iron having reached such a remarkable height, and the last of the advances, in August, having been accompanied by such light sales, the market is simply yielding a competitive amount almost every time an inquiry for an important tonnage arises. Foundry has shown no important inquiry, hence remains quotable nominally at \$45 valley. Basic, which was \$40 valley, yielded, on a 2,000-ton transaction, to \$38.50. An interesting feature of this transaction was that the buyer was entirely out of valley territory, being in the East. Apparently the Eastern furnaces were not quick enough to reduce their quotations. Bessemer has declined from \$45 to \$42 valley, through a furnace interest voluntarily electing to offer iron at the lower price, to avoid bessemer and basic prices being too completely estranged from each other.

Conjectures are now being made as to where pig iron will find its resting or turning point. While steel prices are expected to land at the Industrial Board schedule, the case of pig iron may be different. The Industrial Board prices were: Basic, \$25.75; foundry, \$26.75; bessemer, \$27.95. The furnaces adopted these prices, but under more or less protest, claiming they were too low, relative to steel. The Industrial Board schedule became effective March 21, 1919, and a trifle more than six months later pig iron began to advance, being made scarce by the iron and steel strike. However, a price of \$28 or \$29 in the Industrial Board schedule would have satisfied the furnacemen at the time, as being in suitable relation with steel. Coke, however, not mentioned in the Industrial Board schedule, was obtainable by furnaces to make iron at Industrial Board prices at between \$3.50 and \$4, whereas on account of coal conditions coke seems quite unlikely to decline to anything like that figure. In the past three weeks Connellsville furnace coke for spot shipment has declined from \$17 to \$9, but the decline is beginning to show signs of halting. Coke and pig iron must both find their levels, but the question which is going to control the other proves much more serious than the query as to priority between the chicken and the egg. Common guesses are that pig iron will land somewhere between \$30 and \$35 and coke somewhere between \$6 and \$8.

The Chemical Allied and Industrial Markets

New York, Nov. 6, 1920.

The general condition of the chemical market is hardly active, but is distinctly optimistic—as a result of the election. Price changes, with few exceptions, have continued to favor buyers. *Caustic soda* showed a tendency to resist the downward movement and supplies in the past week have become very light. Manufacturers were quoting \$3.75 per cwt., basis 60 per cent, on contract over next year, with large business transacted among the leading soap makers. The spot market was firm at \$4.30@4.40 per cwt. Another item meriting interest is *bleaching powder*. Rolling material was very scarce, with prices ranging from 6½@6¾c. November shipment from works could be obtained at 6c. lb. Manufacturers reported sales to large paper mills over next year at 3½c. per lb. in large drums f.o.b. works. *Soda ash* seemed to be moving along in sympathy with *caustic soda*. Contracts over next year were placed at \$1.85 per cwt., basis 48 per cent, f.o.b. works. *Bichromate of soda* remained quiet, with a few small sales made at 11½c. per lb. *Bichromate of potash* was one of the weak items with sales recorded as low as 22½c. per lb.

COAL-TAR PRODUCTS

Trading in the coal-tar products market was along quiet lines, and what little business was obtainable was considerably interfered with by election talk. In a great many quarters the general tone is very optimistic, and the hope of an early resumption of activity was more favorably expressed. There were only a few changes in the price list, with *pure benzene* quoted at 35@40c. per gal., and the 90 per cent at 33@38c. per gal. *Cresylic acid* was in easy supply, with the market ranging from 95c.@\$1.15 per gal. Intermediates were in light call with *paranitraniline* as a leading feature. Large orders were on the market at \$1.10 per lb., but holders seemed to expect an active market and were holding for \$1.15 per lb. *Beta naphthol* was quoted over next year at 48@52c. per lb., with very little business obtainable. *Benzoic acid* is in fair demand and supplies are available at 80@85c. per lb.

CRUDE RUBBER

The optimism which is being generally manifested over the outcome of the recent presidential election is utterly lacking in the crude rubber market. *First latex crepe* is quoted at 21c., while the price in January, 1920, was 54c. per lb. This represents a loss of \$660 per ton in less than a year. This condition has been brought about by a combination of circumstances—overestimation by tire producers of this year's consumption, the speculative element that entered the market early in the year and the continued rise in the cost of production of rubber goods. During the last ten months it is estimated twenty firms have failed, some of that number being old-established firms and others fly-by-night speculators that infested the industry. The Rubber Trade Association has seven firms under consideration regarding the settlement of their affairs before entering bankruptcy and ten other cases will come up next week.

In India conditions are still worse. The cost of production to the plantation owner is said to be 27c., while the same material is being offered on the local market at 21c. per lb. The amount of unsold and unused material is estimated at 200,000 tons, which is equivalent to two-thirds the yearly consumption. This surplus is distributed among tire manufacturers, who hold 65,000 tons, local market 35,000 tons, England 30,000 tons and the remainder held in the Far East.

MISCELLANEOUS MATERIALS

There has been a big drop in *coke* during the last two weeks owing to the sudden falling off in demand. Foundry is listed at \$11@11.50 and furnace at \$10@10.50 per net ton f.o.b. ovens. *Tungsten* ore has been quiet for some time, with offerings of \$6 per unit for scheelite and \$4.50@5 for wolframite. These prices do not meet with the approval of buyers, who have been consistently holding out for lower levels.

Sodium chlorate	lb. 14.14 - 14.15	14.15 - 14.16
Sodium cyanide, 96-98 per cent	lb. 28.28 - 28.29	28.29 - 28.30
Sodium fluoride	lb. 20.20 - 20.21	20.21 - 20.22
Sodium hydroxide (caustic soda)	100 lb. 4.30 - 4.40	4.40 - 4.50
Sodium hyposulphate	lb. 0.40 - 0.41	0.41 - 0.42
Sodium molybdate	lb. 2.50 - 2.51	2.51 - 2.52
Sodium nitrate	100 lb. 3.00 - 3.01	3.01 - 3.02
Sodium nitrite	lb. 0.84 - 0.85	0.85 - 0.86
Sodium peroxide, powdered	lb. 50.50 - 50.51	50.51 - 50.52
Sodium phosphate, dibasic	lb. 0.31 - 0.32	0.32 - 0.33
Sodium potassium tartrate (Rochelle salts)	lb. 22.22 - 22.23	22.23 - 22.24
Sodium prussiate, yellow	lb. 0.11 - 0.12	0.12 - 0.13
Sodium silicate, solution (40 deg.)	lb. 0.11 - 0.12	0.12 - 0.13
Sodium silicate, solution (60 deg.)	lb. 0.11 - 0.12	0.12 - 0.13
Sodium sulphate, crystals (Glauber's salt) If 0 lbs	2.15 - 2.50	2.50 - 2.85
Sodium sulphide, crystals, 60-62 per cent (conc.)	lb. 0.7 - 0.71	0.71 - 0.72
Sodium sulphite, crystals	lb. 0.4 - 0.41	0.41 - 0.42
Strontium nitrate, powdered	lb. 20.20 - 20.21	20.21 - 20.22
Sulphur chloride red	lb. 0.8 - 0.9	0.9 - 1.0
Sulphur, crude	ton 16.00 - 20.00	20.00 - 24.00
Sulphur dioxide, liquid, cylinders	lb. 0.9 - 1.0	1.0 - 1.1
Sulphur (sublimed), flour	100 lb. 3.70 - 3.75	3.75 - 3.80
Sulphur, roll (brimstone)	100 lb. 3.40 - 3.45	3.45 - 3.50
Tin bichloride, 50 per cent	lb. 18.18 - 18.19	18.19 - 18.20
Tin oxide	lb. 50.50 - 50.51	50.51 - 50.52
Zinc carbonate, precipitate	lb. 16.16 - 16.17	16.17 - 16.18
Zinc chloride, gran.	lb. 12.12 - 12.13	12.13 - 12.14
Zinc cyanide	lb. 45.45 - 45.46	45.46 - 45.47
Zinc dust	lb. 12.12 - 12.13	12.13 - 12.14
Zinc oxide, XX	lb. 11.11 - 11.12	11.12 - 11.13
Zinc sulphate	lb. 0.31 - 0.32	0.32 - 0.33

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb. \$1.10 - \$1.15
Alpha-naphthol, refined	lb. 1.45 - 1.50
Alpha-naphthylamine	lb. 50.50 - 50.51
Aniline oil, drums extra	lb. 27.27 - 27.28
Aniline salts	lb. 33.33 - 33.34
Anthracene, 80% in drums (100 lb.)	lb. 90.90 - 90.91
Benzaldehyde (f.o.b.)	lb. 2.00 - 2.10
Benzidine, base	lb. 1.15 - 1.20
Benzidine sulphate	lb. 1.10 - 1.15
Benzoic acid, U. S. P.	lb. 80.80 - 80.81
Benzoin of soda, U. S. P.	lb. 80.80 - 80.81
Benzene, pure, water-white, in drums (100 gal.)	gal. 35.35 - 35.36
Benzene, 90%, in drums (100 gal.)	gal. 33.33 - 33.34
Benzyl chloride, 95-97%, refined	lb. 35.35 - 35.36
Benzyl chloride, tech.	lb. 25.25 - 25.26
Beta-naphthol benzoate (nominal)	lb. 3.50 - 4.00
Beta-naphthol, sublimed (nominal)	lb. 90.90 - 90.91
Beta-naphthol, tech (nominal)	lb. 53.53 - 53.54
Beta-naphthylamine, sublimed	lb. 2.25 - 2.40
Cresol, U. S. P., in drums (100 lb.)	lb. 18.18 - 18.19
Ortho-cresol, in drums (100 lb.)	lb. 23.23 - 23.24
Cresylic acid, 97-99%, straw color, in drums	gal. 1.10 - 1.15
Cresylic acid, 95-97%, dark, in drums	gal. 1.05 - 1.10
Cresylic acid, 50%, first quality, drums	gal. 65.65 - 65.66
Dichlorobenzene	lb. 0.7 - 0.71
Diethylaniline	lb. 1.45 - 1.50
Dimethylaniline	lb. 1.00 - 1.05
Dinitrobenzene	lb. 30.30 - 30.31
Dinitrochlorobenzene	lb. 27.27 - 27.28
Dinitronaphthalene	lb. 42.42 - 42.43
Dinitrophenol	lb. 40.40 - 40.41
Dinitrotoluene	lb. 38.38 - 38.39
Dip oil, 25% tar acids, car lots, in drums	gal. 38.38 - 38.39
Diphenylamine (nominal)	lb. 80.80 - 80.81
H-acid (nominal)	lb. 1.65 - 1.70
Meta-phenylenediamine	lb. 1.25 - 1.30
Monochlorobenzene	lb. 18.18 - 18.19
Monethylaniline	lb. 1.75 - 2.25
Naphthalene crushed, in bbls. (250 lb.)	lb. 0.9 - 0.91
Naphthalene, flake	lb. 0.9 - 0.91
Naphthalene, balls	lb. 0.9 - 0.91
Naphthionic acid, crude	lb. 70.70 - 70.71
Nitrobenzene	lb. 12.12 - 12.13
Nitronaphthalene	lb. 40.40 - 40.41
Nitrotoluene	lb. 18.18 - 18.19
Ortho-amidophenol	lb. 3.20 - 3.75
Ortho-dichlorobenzene	lb. 15.15 - 15.16
Ortho-nitrophenol	lb. 75.75 - 75.76
Ortho-nitro-toluene	lb. 25.25 - 25.26
Ortho-toluidine	lb. 32.32 - 32.33
Para-amidophenol, base	lb. 2.50 - 3.00
Para-amidophenol, HCl	lb. 2.50 - 3.00
Para-dichlorobenzene	lb. 10.10 - 10.11
Paranitroaniline	lb. 1.15 - 1.20

Para-nitrotoluene	lb. 1.25 - 1.40
Para-phenylenediamine	lb. 2.50 - 2.65
Para-toluidine	lb. 1.85 - 2.00
Phthalic anhydride	lb. 60.60 - 60.61
Phenol, U. S. P., drums (dest.), (240 lb.)	lb. 12.12 - 12.13
Pyridine	gal. 2.00 - 3.50
Resorcinol, technical	lb. 3.25 - 3.30
Resorcinol, pure	lb. 4.50 - 5.00
Salicylic acid, tech., in bbls. (110 lb.)	lb. 35.35 - 35.36
Salicylic acid, U. S. P.	lb. 40.40 - 40.41
Salol	lb. 85.85 - 85.86
Solvent naphtha, water-white, in drums, 100 gal.	gal. 30.30 - 35.35
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal. 19.19 - 22.22
Sulphanilic acid, crude	lb. 32.32 - 35.35
Toluidine	lb. 1.75 - 1.80
Toluidine, mixed	lb. 45.45 - 55.55
Toluene, in tank cars	gal. 35.35 - 40.40
Toluene, in drums	gal. 41.41 - 42.42
Xylidines, drums, 100 gal.	lb. 50.50 - 65.65
Xylene, pure, in drums	gal. 45.45 - 47.47
Xylene, pure, in tank cars	gal. 45.45 - 47.47
Xylene, commercial, in drums, 100 gal.	gal. 37.37 - 38.38
Xylene, commercial, in tank cars	gal. 30.30 - 35.35

Waxes

Prices based on original packages in large quantities.

Becawax, refined, dark	lb. \$0.30 - \$0.32
Becawax, refined, light	lb. 34.34 - 37.37
Becawax, white pure	lb. 55.55 - 60.60
Carnauba, No. 1, (nominal)	lb. 90.90 - 95.95
Carnauba, No. 2, regular (nominal)	lb. 75.75 - 80.80
Carnauba, No. 3, North Country	lb. 25.25 - 26.26
Japan	lb. 18.18 - 20.20
Montan, crude	lb. 12.12 - 14.14
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb. 0.9 - 0.91
Paraffine waxes, crude, scale 124-126 m.p.	lb. 0.85 - 0.91
Paraffine waxes, refined, 118-120 m.p.	lb. 10.10 - 11.11
Paraffine waxes, refined, 125 m.p.	lb. 11.11 - 12.12
Paraffine waxes, refined, 128-130 m.p.	lb. 12.12 - 13.13
Paraffine waxes, refined, 133-135 m.p.	lb. 15.15 - 16.16
Paraffine waxes, refined, 135-137 m.p.	lb. 16.16 - 17.17
Stearic acid, single pressed	lb. 17.17 - 19.19
Stearic acid, double pressed	lb. 18.18 - 19.19
Stearic acid, triple pressed	lb. 22.22 - 23.23

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940	gal. \$1.90
Pine oil, pure, dest. dist.	gal. 1.50
Pine tar oil, ref., sp. gr. 1.025-1.035	gal. 4.80
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal. 35.35
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal. 85.85
Pine tar, ref., thin, sp. gr. 1.080-1.060	gal. 36.36
Turpentine, crude, sp. gr. 0.900-0.970	gal. 1.75
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990	gal. 35.35
Pine wood creosote, ref.	gal. 52.52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin H-D, bbl	280 lb. \$12.75 - 13.25
Rosin E-L, bbl	280 lb. 12.75 - 13.25
Rosin K-N, bbl	280 lb. 12.75 - 13.25
Rosin W, G-W, W, bbl	280 lb. 13.00 - 13.25
Wood rosin, bbl	280 lb. 11.00 - 11.25
Spirits of turpentine	gal. 1.28 - 1.30
Wood turpentine, steam dist.	gal. 1.22 - 1.25
Wood turpentine, dest. dist.	gal. 1.18 - 1.20
Pine tar pitch, bbl	200 lb. 8.50 - 8.75
Tar, kiln burned, bbl (500 lb.)	bbl. 15.00 - 15.50
Retort tar, bbl	500 lb. 15.00 - 15.50
Rosin oil, first run	gal. 70.70 - 75.75
Rosin oil, second run	gal. 73.73 - 78.78
Rosin oil, third run	gal. 90.90 - 95.95

Solvents

75-76 deg., steel bbls. (85 lb.)	gal. \$0.40
70-72 deg., steel bbls. (85 lb.)	gal. 38.38 - 40.40
68-70 deg., steel bbls. (85 lb.)	gal. 37.37 - 39.39
V. M. and P. naphtha, steel bbls. (85 lb.)	gal. 29.29 - 31.31

Crude Rubber

Para—Priver fine (nominal)	lb. \$0.26 - \$0.261
Priver coarse (nominal)	lb. 17.17 - 18.18
Priver caucho ball (nominal)	lb. 17.17 - 18.18
Plantation—First Intex crepe	lb. 21.21 - 22.22
Bibled smoked sheets	lb. 20.20 - 21.21
Brown crepe, thin, clean	lb. 17.17 - 18.18
Amber crepe No. 1	lb. 19.19 - 20.20

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.	lb. \$0.161 - \$0.18
Castor oil, AA, in bbls.	lb. 15.15 - 16.16
China wood oil, in bbls. (f.o.b. Pac. coast)	lb. 16.16 - 17.17
Cocanut oil, Ceylon grade, in bbls.	lb. 15.15 - 16.16
Cocanut oil, Ceylon grade, in bbls. (nominal)	lb. 17.17 - 18.18
Corn oil, crude, in bbls.	lb. 12.12 - 13.13
Cottonseed oil, crude (f.o.b. mill)	lb. 10.10 - 11.11
Cottonseed oil, summer yellow	lb. 13.13 - 14.14
Cottonseed oil, winter yellow	lb. 15.15 - 16.16
Linsed oil, raw, car lots (domestic)	gal. 1.07 - 1.09
Linsed oil, raw, tank cars (domestic)	gal. 1.00 - 1.02
Linsed oil, boiled, car lots (domestic)	gal. 1.09 - 1.11

Olive oil, commercial.....	gal.	3.00	—	3.50
Palm, Lagos.....	lb.	.10	—	.10
Palm, bright red.....	lb.	—	—	—
Palm, Niger.....	lb.	.09	—	.10
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.10	—	.12
Peanut oil, refined, in bbls.....	lb.	.17	—	.18
Rapeseed oil, refined in bbls.....	gal.	1.30	—	1.45
Rapeseed oil, blown, in bbls.....	gal.	1.60	—	1.70
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.14	—	.14
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.10	—	.11

FISH

Light pressed Menhaden.....	gal.	\$0.80	—	\$0.90
Yellow bleached Menhaden.....	gal.	.83	—	.84
White bleached Menhaden.....	gal.	.86	—	.87
Blown Menhaden.....	gal.	.90	—	1.00

Miscellaneous Materials

All f. o. b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$24.00	—	\$30.00
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	22.00	—	26.00
Barytes, crude, 88% to 94% ba., Kings Creek.....	net ton	10.00	—	12.00
Barytes, floated, f.o.b. St. Louis.....	net ton	26.50	—	28.00
Barytes, crude, first grade, Missouri.....	net ton	10.00	—	—
Blanc fixe, clay.....	lb.	.05	—	.06
Blanc fixe, pulp.....	net ton	60.00	—	60.00
Chalk, domestic, extra light.....	lb.	.05	—	.06
Chalk, domestic, light.....	lb.	.04	—	.05
Chalk, domestic, heavy.....	lb.	.04	—	.05
Chalk, English, extra light.....	lb.	.05	—	.07
Chalk, English, light.....	lb.	.05	—	.06
Chalk, English, dense.....	lb.	.04	—	.05
China clay, (Kaolin) crude, f.o.b. mines, Georgia.....	net ton	9.00	—	12.00
China clay (Kaolin) washed, f.o.b. Georgia.....	net ton	12.00	—	15.00
China clay (Kaolin) powdered, f.o.b. Georgia.....	net ton	18.00	—	22.00
China clay (Kaolin) crude f.o.b. Virginia points.....	net ton	15.00	—	40.00
China clay (Kaolin) ground, f.o.b. Virginia points.....	net ton	25.00	—	35.00
China clay (Kaolin), imported, lump.....	net ton	30.00	—	60.00
China clay (Kaolin), imported, powdered.....	net ton	30.00	—	60.00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	gross ton	8.00	—	14.00
Feldspar, crude, f.o.b. Maine.....	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine.....	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. Baltimore.....	net ton	27.00	—	30.00
Fuller's earth, granular, f.o.b. Fla.....	net ton	25.00	—	—
Fuller's earth, powdered, f.o.b. Fla.....	net ton	18.00	—	—
Fuller's earth, imported, powdered.....	net ton	35.00	—	40.00
Graphite, crucible, 90% carbon, Ashland, Ala.....	lb.	.07	—	.09
Graphite, crucible, 85% carbon, Ashland, Ala.....	lb.	.11	—	.40
Graphite, higher lubricating grades.....	lb.	.04	—	.50
Pumice stone, imported, lump.....	lb.	.06	—	—
Pumice stone, domestic, lump.....	lb.	.06	—	—
Pumice stone, ground.....	lb.	.04	—	.07
Quartz (acid tower) fist to head, f.o.b. Baltimore.....	net ton	—	—	10.00
Quartz (acid tower) 1 1/2 in. f.o.b. Baltimore.....	net ton	—	—	14.00
Quartz (acid tower) rice, f.o.b. Baltimore.....	net ton	—	—	17.00
Quartz, lump, f.o.b. North Carolina.....	net ton	5.00	—	7.50
Shellac, orange fine.....	lb.	—	—	—
Shellac, orange superfine.....	lb.	1.05	—	1.10
Shellac, A. C. garnet.....	lb.	.90	—	.95
Shellac, T. N.....	lb.	.85	—	.95
Soupatone.....	ton	15.00	—	25.00
Talc, paper-making grades, f.o.b. Vermont.....	ton	12.00	—	22.00
Talc, roofing grades, f.o.b. Vermont.....	ton	9.50	—	15.00
Talc, rubber grades, f.o.b. Vermont.....	ton	12.00	—	18.00
Talc, powdered, Southern, f.o.b. cars.....	ton	12.00	—	15.00
Talc, imported.....	ton	60.00	—	70.00
Talc, California Talcum Powder grade.....	ton	20.00	—	35.00

Refractories

Bauxite brick, 56% Al, f.o.b. Pittsburgh.....	1,000	—	160
Chrome brick, f.o.b. Eastern shipping points.....	net ton	100	110
Chrome cement, 40-45% Cr ₂ O ₃	net ton	55	60
Chrome cement, 40-45% Cr ₂ O ₃ , sacks, in car lots, f.o.b. Eastern shipping points.....	net ton	60	65
Fire clay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	—	55-60
Fire clay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	—	45-50
Magnesite brick, 9-in. straight.....	net ton	110	—
Magnesite brick, 9-in. arches, wedges and keys.....	net ton	121	—
Magnesite brick, soaps and splits.....	net ton	134	—
Silica brick, 9-in. sizes, f.o.b. Chicago district.....	1,000	—	65-70
Silica brick, 9-in. sizes, f.o.b. Birmingham district.....	1,000	—	56-61
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa.....	1,000	—	55-60

Ferro-Alloys

All f.o.b. Works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....	net ton	\$200.00	—	\$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon, carlots.....	lb.	.18	—	.19
Ferro-chrome, per lb. of Cr. contained, 4-6% carbon, carlots.....	lb.	.20	—	.21
Ferro-manganese, 76-80% Mn, domestic.....	gross ton	170.00	—	175.00
Ferro-manganese, 76-80% Mn, English.....	gross ton	165.00	—	170.00
Spiegelisen, 18-22% Mn.....	gross ton	75.80	—	80.00
Ferro-molybdenum, 50-60% Mo, per lb. of Mo.....	lb.	2.00	—	2.50
Ferro-silicon, 10-15%.....	gross ton	60.00	—	65.00
Ferro-silicon, 50%.....	gross ton	80.00	—	90.00
Ferro-silicon, 75%.....	gross ton	150.00	—	160.00
Ferro-tungsten, 70-80%, per lb. of contained W.....	lb.	.75	—	.90
Ferro-uranium, 35-50% of U, per lb. of U content lb.....	lb.	7.00	—	—
Ferro-vanadium, 30-40% per lb. of contained V.....	lb.	6.50	—	8.50

Ores and Semi-finished Products

All f.o.b. Mines, Unless Otherwise Stated

Bauxite, 52% Al. content, less than 2% Fe ₂ O ₃ , up to 20% silica, not more than 14% moisture.....	gross ton	\$10.00	—	\$11.00
Chrome ore, Calif. concentrates, 50% min. Cr ₂ O ₃	unit	.70	—	.75
Chrome ore, 50%, max., Cr ₂ O ₃ f.o.b. Atlantic Seaboard.....	unit	.75	—	.85
Coke, foundry, f.o.b. ovens.....	net ton	11.00	—	11.50
Coke, furnace, f.o.b. ovens.....	net ton	10.00	—	10.50
Coke, petroleum, refinery, Atlantic Seaboard.....	net ton	—	—	—
Fluor spar, lump, f.o.b. Tonuco, New Mexico.....	net ton	17.50	—	—
Fluor spar, standard, domestic washed gravel Kentucky and Illinois mines.....	net ton	25.00	—	27.50
Ilmenite, 52% TiO ₂ , per lb. ore.....	lb.	.01	—	.01
Manganese Ore, 50% Mn, c. i. f. Atlantic seaport.....	unit	.60	—	.70
Manganese ore, chemical (MnO ₂).....	gross ton	70.00	—	80.00
Molybdenite, 85% MoS ₂ , per lb. of MoS ₂ , N. Y.....	lb.	.65	—	.70
Monazite, per unit of ThO ₂	unit	35.00	—	—
Pyrites, Spanish, fines, c. i. f. Atlantic seaport.....	unit	.12	—	—
Pyrites, Spanish, furnace size, c. i. f. Atlantic seaport.....	unit	.16	—	—
Pyrites, Spanish, run of mines, c. i. f. Atlantic seaport.....	unit	.12	—	.14
Pyrites, domestic, fines.....	unit	.12	—	.14

Financial, Construction and Manufacturers' News

Construction and Operation

Connecticut

NEW HAVEN—H. Kasden, 19 Hone St., has awarded the contract for the construction of a 1-story, 50x80-ft. addition to his foundry on Mill River St. to J. Skolnick, 159 Columbus Ave. Estimated cost, \$10,000.

PORTLAND—The Wilcox Crittenden & Co., Inc., 8 South Main St., Middletown, plans to build a 1-story foundry. Estimated cost, \$50,000.

Florida

JACKSONVILLE—The William Toomer Fertilizer Co., Vialduet, plans to build a plant to replace the old one recently destroyed by fire. Cost to exceed \$1,000,000. B. M. G. Prange, mgr. Noted June 16.

Illinois

CHICAGO—The Illinois Glass Co., 402 West Randolph St., has awarded the contract for the construction of a 1- and 2-story, 215x270 ft. factory, at 2601 North Crawford Ave., to Dahl Stedman Co., 11 South La Salle St.

CHICAGO—Stearns Bros. & Co., 619 South La Salle St., will soon award the contract for the construction of a 3-story, 100x160-ft. printing plant, on East Huron St. and Fairbanks Court. Estimated cost, \$200,000. Berlin, Swern & Randall, 19 South La Salle St., archts.

ROCKFORD—The city plans to construct intercepting sewers at a cost of about \$600,000 and settling tanks and chlorination plant at a cost of about \$220,000.

Indiana

ANDERSON—The Lavelle Foundry Co. is building a factory for the manufacture of gray iron castings. General foundry equipment and pattern shop machinery will be installed in same. J. F. Stanley, 1225 North Alabama St., Indianapolis, engr.

ELKHART—The Wawasee Tire & Rubber Co. will soon award the contract for the construction of a 4-story, 175x175-ft. factory. Estimated cost, \$500,000. R. L. Simmons, archt.

FORT WAYNE—Griffith & Goodrich, archts., Physician's Defense Bldg., will receive bids about Nov. 25 for the construction of a 1- and 2-story, 60x180-ft. factory on Cochran St., for the Amer. Textile Art Printing & Dyeing Co., 403 West Jefferson St. A water filtering and softening plant to have a capacity of 10,000 gal. in 8 hours will be installed in same. Estimated cost, \$40,000.

Maryland

BALTIMORE—The H. B. Hearn Co., 41 South Gay St., plans to build a plant for the manufacture of chemical mixtures, etc., electrically operated, to turn out about 25 bbl. of sweeping mixture daily. H. B. Hearn, pres. and mgr.

Massachusetts

BOSTON—The Amer. Can Co., 120 Bway., plans to build a factory. Estimated cost, \$250,000.

BOSTON—K. J. Quinn & Co., Inc., 80 Batterymarch St., will soon award the contract for the construction of a 2-story, 30x60-ft. addition to shoe polish factory. Cost, between \$18,000 and \$20,000.

HOLYOKE—The Amer. Writing Paper Co., 9 Main St., will build a 1-story, 25x75-ft. addition to its paper factory. Estimated cost, \$25,000. Work will be done by day labor.

HOLYOKE—The Worthington Pump & Machinery Corp., 37 Appleton St., will soon award the contract for remodeling old schoolhouse into pattern plant, on North Bridge and East Dwight Sts. Estimated cost, \$30,000.

Michigan

* **CADILLAC**—The Mercy Hospital is having plans prepared for the construction of a 3-story addition to present hospital. A chemical laboratory will be installed in same. Estimated cost, \$100,000. E. Brielmaler Sons, University Bldg., Milwaukee, Wis., archts. and engr.

Minnesota

FRIDLEY—The Walsh Tie Co., 951 McKnight Bldg., Minneapolis, has awarded the contract for the construction of a cross-cutting plant to include an office building, factory, power house, retort tanks, etc., to C. F. Haglin & Sons, 226 Lumber Exch., Minneapolis.

LONG PRAIRIE—Indian School Dist. 11 will soon award the contract for the construction of a 2-story, 75x160-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$200,000. W. M. Barber, secy., C. Howard Parsons, 600 Builders Exch., Minneapolis, archt.

MANKATO—The Carney Cement Co. is having plans prepared for the construction of a cement plant, to include a mill building, machine shop, blacksmith shop, chemist's building, 16 steel kilns to measure 60 ft. high and 18 ft. in diameter, etc., north of here. Estimated cost, \$150,000. R. K. Meade, 11 East Fayette St., Baltimore Md., engr.

Nebraska

CHADRON—The City Council will receive bids until Nov. 15 for the construction of a complete sewage disposal plant, to include a septic tank, sand filter, etc. Estimated cost, \$50,000. R. D. Salisbury Co., 1600 Downing St., Denver, Col., engr.

LINCOLN—Alvord & Burdick, engr., 8 South Dearborn St., Chicago, are preparing plans for the installation of a sewage disposal plant here. Estimated cost, \$330,000.

New Jersey

MAURER—The Barber Asphalt Paving Co., 233 Bway, New York City, has awarded the contract for the construction of a 2-story asphalt plant, to Levering & Garriques, 552 West 23d St., New York City.

TRENTON—The Star Porcelain Co., Mulhead Ave., has awarded the contract for the construction of a 2-story, 40x80-ft. addition to its factory, to C. R. Randall, 43 North Hermitage St. Estimated cost, \$6,500.

New York

BROOKLYN—The Grand Corrugated Paper Co., 30 Crosby St., has awarded the contract for altering its factory on 32d St. to the Gabler Constr. Co., 402 Hudson St., New York City. Estimated cost, \$50,000. Noted Oct. 13.

NEW YORK—Paul Schuldeberger will alter the 5-story factory for the manufacture of brushes at 52 Cliff St. Estimated cost, \$35,000. Work will be done by day labor.

North Carolina

GREENSBORO—The Carolina Steel & Iron Co. plans to build an 80x180-ft. foundry. Estimated cost, \$25,000.

WILMINGTON—The Fisheries Products Co. plans to build a fertilizer plant. Estimated cost, \$100,000.

Ohio

CLEVELAND—The Mulay Rubber Co., 1035 Guardian Bldg., plans to build a 3-story factory on East 172d St. and St. Clair Ave. Estimated cost, \$100,000.

CLEVELAND—Parish & Bingham Co., manufacturers of castings, 11600 Madison Ave., has awarded the contract for the construction of a 1-story, 24x45-ft. heating room, to the E. C. Gaspard Constr. Co., Engineers Bldg. Estimated cost, \$10,000.

KENT—The Bd. Educ. is having plans prepared for the construction of a 2-story, 160x200-ft. high school. A chemical laboratory will be installed in same. Esti-

mated cost, \$275,000. Mills & Millsbaugh, 67 East Long St., Columbus, O., archts.

MANSFIELD—The Superior Brass Mfg. Co. is building a 40x60-ft. addition to its foundry. Estimated cost, \$11,000. E. K. Bacon, secy., Althouse & Jones, engr.

YOUNGSTOWN—The Reserve Iron & Steel Co. plans to build two blast furnaces and a 2,000,000 puddling plant. Estimated cost, \$1,000,000.

Pennsylvania

PHILADELPHIA—Baeder & Adamson Co., Richmond and Allegheny Sts., will alter and build a 1-story, 50x120 ft. addition to its present factory for the manufacture of glue. Estimated cost, \$56,000.

PHILADELPHIA—Clark & Dudnick, archts. and engr., Drexel Bldg., will soon award the contract for the construction of a 1-story foundry and woodworking shop on 32d and Walnut Sts. Owner's name withheld.

PITTSBURGH—The Pittsburgh Malleable Iron Co., 57th St. and the Allegheny River, plans to build a 202x322-ft. foundry. Estimated cost, \$500,000. F. Chase, 615 North Michigan Ave., Chicago, archt.

Texas

DALLAS—The Lincoln Paint & Color Co., Detroit, Mich., has awarded the contract for the construction of the first unit of its paint factory to be 2-story, 140x180 ft., on Kentucky and Ash Lane, to E. R. Sessums & Sons, Detroit, Mich. Estimated cost, \$150,000.

WICHITA FALLS—The State Bd. of Control, Austin, has awarded the contract for the construction of a sewage disposal plant at the Northwest Insane Asylum here, to the James Constr. Co., Dallas, at \$47,700.

West Virginia

HUNTINGTON—The International Nickel Co., 43 Exch. Pl., New York City, will build a rolling mill plant. Estimated cost, \$3,000,000.

Wisconsin

DRUMMOND—The Rust-Owen Lumber Co. is having preliminary plans prepared for the development of the sewer system, to include the construction of a sewage disposal plant, garage and several small buildings. Estimated cost, \$100,000. R. E. Christ, secy. and treas. G. Lister Nason, 641 Endicott Bldg., St. Paul, archt.

RACINE—Alvord & Burdick, engr., 8 South Dearborn St., Chicago, have submitted a report recommending the abandonment of the present water station and the installation of new pumps, filtration plants and a 36-in. intake from Lake Michigan and about \$400,000 of additional distribution system. Estimated cost, \$2,000,000.

SCHLESINGERVILLE—The Zwebel Bros. Co. will soon award the contract for the construction of a 1-story, 60x150-ft. factory for the manufacture of vulcan outfits. Estimated cost, \$100,000. Judd & Hogner, 415 Milwaukee St., archts.

Quebec

COLERAIN—The Canada Asbestos and Chrome Co., Ltd., is in the market for equipment.

MONTREAL—The Canada Cement Co., Herald Bldg., Craig St., West, plans to build a 10-story building. Estimated cost, \$450,000. Ron & MacDonald, Belmont St., archts.

MONTMAGNY—The Malleable Foundries, Ltd., will receive bids about Nov. 15 for the construction of a foundry. Estimated cost, \$75,000.

MONTREAL—Taylor & Arnold Eng. Co., Ltd., 39 Oiler St., plans to build a brass foundry and install equipment in same.

Alberta

EDMONTON—The San Francisco & McMillan Oil Co., Ltd., plans to build a plant. Estimated cost, \$500,000.

New Publications

NEW BUREAU OF STANDARDS PUBLICATIONS: Scientific Paper 386, Atomic Theory and Low-Voltage Arcs in Cesium Vapor, by Paul D. Foote and W. F. Meggers; Scientific Paper 387, Permeability of Rubber to Gases, by Junius David Edwards and S. P. Pickering; Scientific Paper 392, A Photographic Method of Detecting Changes in a Complicated Group of Objects, by M. H. Stillman; Tech. Paper 164, Saybolt Viscosity of Blends, by Winslow H.

Herschel; Tech. Paper 165, Enamels for Sheet Iron and Steel, by J. B. Shaw.

NEW BUREAU OF MINES PUBLICATIONS: Bull. 182, Casing Troubles and Fishing Methods in Oil Wells, by Thomas Curtin; Tech. Paper 230, Determination of Molybdenum, by J. P. Bonardi and Edward P. Barrett; Tech. Paper 233, The Properties of Some Stoneware Clays, by H. G. Schurecht; Tech. Paper 238, Indicators for Carbon Dioxide and Oxygen in Air and Flue Gas, by L. H. Milligan, D. O. Crites and W. S. Wilson; Tech. Paper 244, Use of Stenches as a Warning in Mines, by S. H. Katz, V. C. Allison and W. L. Egy; Tech. Paper 266, Coke-Oven Accidents in the United States During the Calendar Year 1919, by William W. Adams.

NEW UNITED STATES GEOLOGICAL SURVEY PUBLICATIONS: Mineral Resources of the U. S. in 1919 (Preliminary Summary), Introduction by G. F. Loughlin, statistics assembled by Martha B. Clark, published Sept. 8, 1920; I: C, Mineral Production of the U. S. in 1917, Introduction by H. D. McCaskey, summary by Martha B. Clark (Mineral Resources of the U. S., 1917, Part I), published June 28, 1920; 1: 24 Gold and Silver in 1918 (General Report), by J. P. Dunlop (Mineral Resources of the U. S., 1918, Part I), published July 15, 1920; 1: 28, Land in 1917, by C. E. Sieben-thal (Mineral Resources of the U. S., 1917, Part I), published May 8, 1920.

NEW UNITED STATES TARIFF COMMISSION PUBLICATIONS: Tariff Inf. Series No. 18, Barytes, Barium Chemical, and Lithopone Industries, Including Costs of Production, 1919.

UNIVERSITY OF HEAT FROM VARIOUS SURFACES, by V. S. Day, Bull. 118, published by the University of Illinois, Urbana, Ill. Price 20c.

THE MINERAL INDUSTRY OF THE BRITISH EMPIRE AND FOREIGN COUNTRIES, NITRATES, published by the Imperial Mineral Resources Bureau, London. Price 9d.

DATA BOOK FOR ENGINEERS, published by the Locomotive Superheater Co., New York. This book has been compiled for the purpose of assisting stationary engineers in their everyday work by furnishing them with useful data. Copies will be sent to anyone actually interested in steam engineering.

Manufacturers' Catalogs

THE GAS PRODUCER & ENGINEERING CORP. of New Jersey, New York City, has issued Bull. 96, on Gashua Suction Type "T" Stationary Gas Producer. Descriptive matter and illustrations are given.

THE TECHNICAL PRODUCTS CO., INC., New York, dealer in new and used equipment, the latter comprising large purchases from Government munitions plants, has recently issued an attractive folder entitled the A B C's of Refrigeration, describing, under the caption of "The Technical Way," the high-speed vertical single acting ring plate valve compressors, which it is handling. Copies can be obtained by addressing the company at its main office, 501 Fifth Ave., New York City.

THE MAGNESIA ASSOCIATION OF AMERICA, Philadelphia, Pa., has published a new book on heat insulation entitled "Defend Your Steam," by Austen Bolam. The book presents the result of four years of original research by the association and the Mellon Institute and covers every phase of heat- and fuel-saving with 85 per cent magnesia pipe and boiler covering. It is well illustrated and contains a variety of data and information on heat and heat losses.

INVER-HARRIS CO., Harrison, N. J., has published an excellent booklet entitled "Case Carbonizing." Chapters are devoted to cyanide hardening, gas hardening, lead tempering and hardening, nichrome containers, etc. The booklet is written in language that will be readily understood by the heat treater and will give him the results of the latest scientific investigations in this branch of metallurgy.

THE WEBSTER MFG. CO., 4500 Cortland St., Chicago, has issued the October, 1920, number of "Webster Method," containing articles on recent interesting installations in the materials-handling field. "Webster Method" has been issued since 1911. Its numbers contain descriptions and photographs of recent installations in the coal, grain, mining, chemical and other fields, in which conveying apparatus form so large a factor in conserving hand labor. The subjects of its articles cover not only installations which solve labor handling problems in the United States but often include installations which have been made in for-

eign countries. "Webster Method" is published regularly and distributed free to those who are interested in labor conserving methods.

THE ATERITE CO., INC., New York City calls attention to Bull. 7 on "Aterite Rods and Sheets, Cold Rolled—Cold Drawn." Many interesting illustrations are given, with descriptions and tables of weight of rolled Aterite rods, sheets and plates, and a table showing comparison of different gages, together with equivalent in decimal parts of an inch.

WORTHINGTON PUMP & MACHINERY CO., New York, announces Catalog BK-3,000, illustrating and describing Worthington Marine Pumps and Auxiliaries. The catalog consists of one hundred and twenty-five pages of descriptive matter and illustrations, and should be a comprehensive and useful publication to marine circles generally.

CRESCENT SALES & ENGINEERING CO., Detroit, Mich., calls attention to a new catalog on Crescent "Roto-Piston" Vacuum and Pressure Pumps. The booklet contains descriptions of Roto-Piston vacuum pump and blower, pump description and performance, view of assembling department, uses of pumps, description of operation phantom of pumps and parts, vacuum chucks, special pumps, vacuum time curves, pressure curves, vacuum pump data, details of foundation, etc., list of parts and instructions for installing and operating.

THE ACHESON GRAPHITE CO., Niagara Falls, N. Y., announces a new publication entitled "Electric Furnaces." Section I deals with electric furnaces made in the United States and Canada and Section II with electric furnaces made in the United Kingdom and Continental Europe. Illustrations are given of many of the furnaces.

BUFFALO FOUNDRY & MACHINE CO., Buffalo, N. Y., recently issued an attractive booklet on "Some Recent Developments in Bufovak and Bufokast Apparatus." The booklet covers some recent developments in vacuum driers, evaporators, vacuum pans, chemical equipment, sugar apparatus, etc.

BLAW-KNOX CO., Pittsburgh, Pa., has issued two new folders entitled "Blaw Bulldog Buckets" and "A Discussion of Lever Arms."

ELECTRO BLEACHING GAS CO., New York City, has published a new textile bleaching booklet entitled "Liquid Chlorine." This attractive catalog contains various formulas used for the making up of a bleaching solution from liquid chlorine.

CUTLER-HAMMER MFG. CO., Milwaukee, Wis., calls attention to Pub. 860, which takes up in a general way the control of motor-driven pumps and compressors on water and compressed air systems, in mines, on board ships, for hydraulic elevators, etc. Every C-H product used for this class of service is described, including manual and automatic starters and speed regulators, and accessories, such as pressure regulators, float switches, push buttons, etc. A condensed chart is given to aid in the selection of the proper control equipment for each particular class of service.

THE DINGS MAGNETIC SEPARATOR CO., of Milwaukee, Wis., has issued Bull. 81, describing several types of magnetic separators. Among these is included the new Type C magnetic separator, which is designed for separating fine granular material. It is of the medium intensity and cross-belt type, and is used for extracting iron from brass and aluminum borings and turnings, iron from glass sand, abrasive material, rubber buffings, fireclay, cattle and poultry food, phonograph record material, etc. The material to be separated passes through two positive magnetic zones.

THE SPECIAL CHEMICAL CO., of Highland, Ill., has issued a new bulletin on Pfau-stichl sugars, which are used in bacteriology for differentiating various disease-producing micro-organisms.

THE ARTHUR R. MAAS LABORATORIES, Los Angeles, Cal., has issued an attractive catalog on "Chemistry and You," which is published for the purpose of acquainting the reader of its business—chemical service. This booklet contains interesting write-ups on: The Misunderstood Chemist; Yesterday and Tomorrow; Lazy Materials; Sherlock and the Chemist; Counting the Bugs; Buying on Faith; Chemical Specifications; Our National Beverage; Gasoline vs. Coal Oil; The Chemical Alphabet; Exit Snails; Wasted Advertising; Insurance Adjustments; Chemical Gold Bricks; The Wrong Foot First; From Test Tube to Factory; Unhatched Dollars; Profits in Waste; Before Judge and Jury; Chemical Advertising and a Word About Ourselves.

THE DENVER FIRE CLAY CO., Denver, Col., has just received from the press a 32-page

illustrated bulletin on Oil Shale Equipment. At first is a brief review of the shale-oil industries in Scotland, and a description showing occurrence of oil shale in the United States. Following this are a number of illustrated methods for the preliminary or field distillation of oil shale, and also lists and descriptions of apparatus used in the oil shale industries, followed by a number of oil shale retorts and plants.

THE AJAX METAL CO., Philadelphia, Pa., calls attention to its new export catalog which has been published in two editions, one English and one Spanish. The text and illustrations are in both cases identical. This book covers all Ajax products from Babbitt metals to cast brasses and castings, and ingot metal, and is a comprehensive book on the metal field for export use. The book is illustrated.

MANIERRE ENGINEERING & MACHINERY CO., Milwaukee, Wis., has just issued its 1920 catalog, which contains illustrations of the latest installation of the company's seven different types of loaders, showing the wide application of these machines in the United States and Canada.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1920 meeting Dec. 27, 1920, to Jan. 1, 1921, at Chicago, Ill.

AMERICAN ASSOCIATION OF ENGINEERS will hold a meeting on employment and education in the Congress Hotel, Chicago, on Nov. 12.

AMERICAN CERAMIC SOCIETY will hold its annual meeting the week of Feb. 21, 1921, at Columbus, Ohio, with headquarters at the Deschler Hotel.

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29, 1921.

AMERICAN GAS ASSOCIATION will hold its second annual convention at the Hotel Pennsylvania, New York, Nov. 15 to 20.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its winter meeting at New Orleans, Dec. 6 to 9. Headquarters will be at the Hotel St. Charles.

AMERICAN MINING CONGRESS will hold its next convention in Denver Nov. 15 to 19.

AMERICAN PETROLEUM INSTITUTE will hold its annual meeting on Nov. 17, 18 and 19, in Washington, D. C. Headquarters will be at the New Willard Hotel.

AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS' 1920 annual meeting will be held in the Engineering Societies' Building from Dec. 7 to 10 inclusive.

FEDERATED AMERICAN ENGINEERING SOCIETIES will hold its first meeting in Washington, D. C., Nov. 18 and 19. American Engineering Council will hold its organizational meeting Nov. 20. Headquarters for both will be at the New Willard Hotel.

PHILADELPHIA SECTION, AMERICAN CHEMICAL SOCIETY will hold its regular meeting Nov. 18 at the Engineers' Club, Philadelphia. Ellwood Hendrick will speak on "Relativity and Life."

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: Nov. 19, American Chemical Society; Dec. 10, American Chemical Society, joint meeting with Society of Chemical Industry, American Electrochemical Society and Société de Chimie Industrielle; Jan. 7, American Chemical Society; Jan. 14, Society of Chemical Industry, Perkin Medal award; Feb. 11, American Electrochemical Society, joint meeting with Society of Chemical Industry, American Chemical Society and Société de Chimie Industrielle; March 11, American Chemical Society, Nichols Medal award; March 25, Society of Chemical Industry; April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry, and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Number 20

The Goose Or the Egg

ABANDONMENT or curtailment of research by certain industrial laboratories is reported or rumored frequently of late. The psychology of the times, both present and recent past, partly explains this; but it is by no means a justification of the tendency. It is simply another instance of killing the goose which lays the golden egg.

During the war period we had a most wonderful demonstration of the effectiveness of industrial research. Many industries profited beyond their wildest dreams from technical investigations then undertaken for the first time. One would think that these at least would have been thoroughly "sold on the idea." It appears, however, that even some such organizations feel that they now know enough to do without further research.

Perhaps one of the most serious causes of research curtailment has been the fact that many inadequately trained, inexperienced chemists have gone into this field and undertaken to do work which was beyond their capabilities.

A generation ago we spoke of a man as a scientist and the term had a definite meaning. A decade ago the term "chemist" was of rather specific significance; today, however, it is necessary to qualify very materially the term "chemist" before one can really comprehend clearly the field to which such professional worker is suited. We not only need to specify whether it be in organic, inorganic, physical or electro chemistry or other similar field, but also we must specify whether it be in so-called "pure" research, industrial research, plant control or other application of the specialized branch of chemistry that the experience and fitness of the worker lies. It is perhaps desirable, certainly inevitable, that those poorly qualified for industrial research organizations should be eliminated at an early date. However, it is to be hoped that a mad campaign of economy will not cut off what should be in the long run one of the most profitable branches of the industry—namely, the research division.

In consideration of a research organization, the industrial executive should understand that it is not at all like other departments which within a short time can be expected to show profit, with discontinuance or reorganization as a penalty for failure. Research requires extended periods of preliminary work, often apparently unprofitable. A great many trials must be made which give only negative results. Often the executive fails to realize that these negative results may be more valuable in avoiding errors of plant design or operation than positive constructive conclusions. In the end, however, well organized, properly directed research will pay.

There is no industry which we need to except when making this statement.

We have ample demonstration in large corporate laboratories, such as that of the General Electric Company, that intelligently managed "big business" knows the profit of a research organization working on fundamental problems which sooner or later will be of advantage to the industry. In another branch of electrical operations the tungsten filament lamp is found a product of pure research. This did not come about early in the work; it was rather the outgrowth of long investigation which at many stages was doubtless discouraging. Other industries will have similar experiences and other industries, if they will but be conservative in their urgent demands upon research, will correspondingly profit.

Let us keep the goose alive even if it does mean that we must go and draw a bit from our savings account in order to buy cracked corn and ground bone (or whatever food it is that this kind of a goose may need) in order that we may hope for our golden eggs.

Increasing Output By Preventing Disease

IF THE average business man were to read in his morning paper tomorrow that there had just been discovered 1,000,000 cases of smallpox in the United States, he probably would close up his factory or office and move his family to seclusion in the country and develop a state of panicky interest characteristic of our American people. On the other hand, he reads the statement that there are 1,000,000 cases of tuberculosis in the United States today and it does not excite him a bit. Why? Smallpox is a fatal, quickly developing, acute disease; tuberculosis is a chronic, slowly developing, long-drawn-out malady. And yet the economic loss as well as the loss in other ways from tuberculosis is vastly greater in one year than the loss from smallpox for two centuries.

Consider for a moment what 1,000,000 sick consumptives implies as it relates to industry. While accurate figures are not available, it is a conservative estimate that at least 800,000 of the million are workingmen and workingwomen. Probably the percentage is higher. If everyone of them lost on an average only fifty cents a day in production to themselves and their employers, the total daily loss would be \$400,000. That this is a conservative figure any employer of large groups of men will agree. A sick man, whether he is in bed or whether he is at his bench as a producer, costs money to himself, to his employer and to his community.

Take the situation in some of the metal trades for example. Ten per cent more foundrymen and molders die of tuberculosis between the ages of twenty-five and

forty-four than do men generally in the same age periods. This means that in the years of greatest productivity more men die in this industry of tuberculosis than in other groups. Of workers exposed to metallic dust in general, of which there are many thousands between the ages of twenty-five and forty-four, 5 per cent more die of tuberculosis than among workingmen in general and 10 per cent more than among farmers, to contrast them with one of the particularly favored groups. Again, 21 per cent of the deaths in this large group are caused by tuberculosis; or to take a more specific group, among iron and steel workers 16.9 per cent of all deaths are caused by tuberculosis.

Investigations by FREDERICK L. HOFFMAN in this country and by Sir THOMAS OLIVER in England and by many others in various parts of the world have clearly shown that constant exposure of workingmen to metallic dust and to chemical fumes leads to increased tuberculosis.

The reason for this is not far to seek. Tuberculosis is caused by a germ that usually enters the body in early childhood. Most men carry the germs of tuberculosis hidden away in their bodies before they reach the age of twenty-one. Whenever the tissues of the lungs or other tissues of the body become weakened by disease, self-indulgence or by the constant irritation of some substance such as fine metal dust particles or gassy fumes, the soil is prepared and the latent, already-present germ begins to develop an active process and under these favorable conditions the disease known as tuberculosis definitely sets in.

The problem of tuberculosis in industry, therefore, resolves itself into these two definite phases: First, the prevention of infection. This involves safeguards against spitting, sneezing and coughing by providing proper receptacles, by constant education, by periodic medical examination and otherwise. Second, by building up and maintaining resistance to the highest notch of efficiency. This requires not only constant medical supervision and continuous education but the development of the best community activities for recreation. It implies also that the workingman shall have not only proper working conditions but sufficient money with which to buy proper living conditions, including house, food and clothing, for himself and his family. Anything that goes to the building up and making of health increases production and produces more revenue for the employer.

It has been estimated by the National Tuberculosis Association that on an average two and one-half years of life could be added to the mean after life-time of every individual in the United States if tuberculosis could be removed as a cause of death. This would mean a gross saving of at least \$25,000,000,000 to the industries and people of this country. To eliminate the disease would cost probably in the neighborhood of \$2,000,000,000. Consequently any agency or movement which has this accomplishment as its purpose is worthy of widespread individual and organized support. The purpose of the National Tuberculosis Association and its allied agencies is to unite communities all over the United States, in order to secure the machinery and assistance necessary to prevent tuberculosis. The revenue for this great health- and life-saving movement is provided from the annual sale of Christmas Seals from Dec. 1 to 11.

Every dollar's worth of seals aims a strong blow at this disease.

Industrial Autocracy And the Way Out

WILLIAM B. DICKSON, vice-president of the Midvale Steel & Ordnance Co., is the one man in the steel industry who has spoken out and said, what many no doubt have thought, that the present industrial system represents an autocracy in the control of the employers over the employees. Speaking at the fortieth anniversary of the American Society of Mechanical Engineers, Nov. 5, Mr. DICKSON referred in particular to the policy of the United States Steel Corporation, calling it a benevolent autocracy, benevolent in many splendid ways, but still an autocracy, and saying further: "The autocratic policy of this great industrial corporation is diametrically opposed to American ideals, and if it and similar organizations in other industries continue to grow and to maintain this autocratic attitude, there can be only one result—industrial feudalism, feudalism with a high degree of comfort and safety for the worker, I grant you, but none the less feudalism." The feudal barons owned the land and its appurtenances, the highways, streams, mines, fisheries, etc., while at the present day the corporations own plants.

Mr. DICKSON says American industry has now come to the parting of the ways, one way leading to industrial democracy, the other, camouflaged to appear as the natural continuance of the present road, leading to industrial feudalism, but with a bypath "now being trodden by Russia, and toward which not only our British brethren but a considerable number of American workmen are being tempted to stray."

Feudalism is cited as a horrible example of what the present industrial system represents or is trending toward. If, then, one should set up the problem, "How would you devise a way out of feudalism?" one reasonable suggestion would have been that the barons and workers should go into partnership and should divide the proceeds by shares. In the modern partnership the partners divide the profits according to a predetermined schedule.

Now it chanced that the steel mills have had in practice for a long time this very system, only that it is not general. It is curious that Mr. DICKSON did not propose an extension of the system, so successful where it has been used, to all the workers. We refer, of course, to the "tonnage" basis of payment, and particularly to those systems in which the rate per ton varies according to the market or selling price of the material produced. That is vastly better than any so-called system of "profit sharing." Profits may be reduced by the mistake of a purchasing agent and the worker should not be expected to contribute toward the loss. The system is really a very common one. While in some cases the tonnage rate does not fluctuate with selling prices, that is doubtless because the workman does not wish to have it so. The system can be extended. Works managers are certainly ingenious enough to solve the problem. Where the work is collective a total sum could be allotted and the men be permitted to determine how many they desired should divide the pool. A blast furnace could then be operated with fewer men. That would be industrial democracy, a partnership among capital, management and labor, with the public sharing in the general prosperity that would inevitably accompany so happy a solution of the problem.

Why Not Turn The Mold Over?

RECENTLY in these pages the opinion was expressed that the American steel industry, speaking generally, was impelled by a desire for great tonnage rather than great quality. Such a state of affairs opposes the ideals of metallurgists, who quite naturally by their training, work first for excellence.

Sound steel—free of cavities, cracks, excessive segregation and non-metallic inclusions—is a difficult thing to make and precious. It would be a high goal for the ambition of many steel producers. Yet it is being made in this country in considerable quantity. Its makers realize that steel is not steel until it is successfully cast; given the best furnace practice at their command, making well settled and thoroughly deoxidized steel, they still exercise the most extreme care in getting it into the molds.

Take high-grade forging ingots as an illustration. Metal would probably be tapped into a clean, preheated ladle, running from the furnace somewhat too hot to pour. Fifteen or twenty minutes' cooling in the ladle allows trapped slag to separate cleanly. Ingots would probably be bottom-poured through runners proportioned so that the minimum of air would be drawn in with the steel by injector action, and poured just hot enough and fast enough that the surface of the metal rising in the mold would float islands of chilled metal like films of cream floating on milk. Molds themselves would be prepared and cleaned with the greatest care, so the advantages from complete lack of splattering might not be lost through particles of foreign matter, or the hot ingot sticking to the sides of a roughened mold. The mold itself would doubtless be bigger at the top than at the bottom, with thick bottom walls for great chill, thus insuring progressive freezing from bottom upward. Further to guard against secondary pipe, a sink-head of brick would be built on top the ingot, and charcoal or slag would be placed on top the liquid metal to retain it molten as long as possible. Such ingots would be lifted out of their molds while still red, and buried or soaked to insure slow cooling and prevent shrinkage cracking.

"But," it is objected, "this program is entirely too expensive for cheap products which do not require such high quality." Granted; but where does this idea lead?

You would make the steel in the ladle (or even in the ingot) rather than in the furnace, in order to increase the tonnage of the plant; you would cast fast and cold to enable the ingot to stand more abuse in blooming; the molds would be bigger below than on top because they are easier to strip; you would top-cast because it is cheap, and generally neglect the sink-head or hot top for the same reason; you would strip as soon as possible and remove to a soaking pit to save heat and perchance cure some of the ready made imperfections, and rush the rolling by heavy drafts to avoid reheating. In other words these things are exactly what a maker of quality steel does not do.

Generally speaking, when an American plant must produce sound metal, really sound, such as will make high-explosive shell forgings, it casts dead-melted steel and the Government will accept about 55 per cent of the ingot. If an English plant would cast the same metal it would be done in such a way that 85 per cent would be acceptable by inspectors no less keen to find

defects. It is not because we do not know how. Unquestionably the only reason American plants persist in making ingots with internal cavities is because only about one-eighth of their total production is dead-melted steel and of this they are able to work off on unexact purchasers up to half what is defective and should really be discarded.

Evidently, a seeker for sound ingots—really sound—must disregard particular plant layouts, big outputs and apparent economies. His way unquestionably will be hard, but he will be assisted by the inevitable trend of future demand, and eventually he will succeed.

With so many points of attack it is only necessary for one desirous of increasing ingot quality to select the most vulnerable and the one most likely to yield the greatest results for the energy expended. That appears to be the taper of the molds. Apparently a small point, but it has been so often demonstrated by theory and practice that in a big-end-up ingot the pipe is shorter and higher up, as compared to the same mold inverted, that no discussion of the reasons is necessary here. Big-end-up ingots have been used in France and Germany for forty years or more; their use has always been one of the causes of the excellence of Swedish metal, and, impelled by war's demands, the English have widely adopted the practice in these recent years. Even Americans use the idea to the extent of making perhaps a million tons a year, mostly in highest-grade forging ingots, or high-carbon or alloy steels. But even so, some notable pioneers have even discovered that it pays on the more common grades.

Many special methods of reducing pipe and limiting segregation have been regularly used in American mills for the past five years. But they have all compromised with the big-end-down fetish. Their users have realized that to prevent a pipe you must feed it, and therefore simulate the clay "dozzle" with which the crucible steel melter caps his mold, by making it thin at the top, insulating it with fireclay, building sink-heads, or actually heating the top by outside flame. But they seemingly have dodged the fact that a big-end-up casting provided in itself an upper reservoir of metal hot to the last, and which, if assisted by their ingenious sink-heads, would without peradventure absolutely prevent secondary pipe and give up to 85 per cent "sound" metal, something their half-way steps have not yet insured.

It is not the intention to lecture the American metallurgist on the exact procedure he must follow in furnace, casting, molds and soaking in order to eliminate internal cavities. It is the intention, however, to emphasize as clearly as possible that most of the present defects are due to the lack of discrimination among American steel users, and the insistent demand for tonnage production from the steel-works' management. We hold no brief for HADFIELD, GATHMANN, BRADFORD, or any of those sturdy men, except in our poor way to support their efforts toward getting sound metal. We have tried to point out that American steel-making practice has had the tonnage idea for a goal. It is time now to look for quality. We propose a forward step which need not be postponed years—in case a manager wanted to do it it could be done within a month.

As one might say, "Turn the mold over."

Notes on French Industries

FROM OUR PARIS CORRESPONDENT

Paris, France, Oct. 15, 1920.

A GREAT number of our people persist in qualifying as abnormal our present economic situation. In fact, after the cataclysm we passed through during the last few years, we and all the rest of the world find ourselves today in quite a logically resultant situation. It is wrong to compare our present status with that of the pre-war period, because it is bound to create a pessimistic spirit at a time when we need to be so very optimistic.

These reflections are the more apparent now when we are threatened with a very grave and profound economic crisis. Credit is becoming more and more restricted and the money stringency has already reached a very acute stage. A great number of manufacturers, fearing an endless rise in prices of raw materials, have accumulated enormous stocks at high prices, and have transformed these expensive materials into finished products at high costs; but now when a general decline in prices is expected and the demand for the finished products has fallen until it has quite disappeared, manufacturers and consumers find themselves in a peculiar position. The manufacturers do not wish to sell at a loss, and the consumers delay their buying as long as they can.

The fall in prices has already begun; it started with metallurgical products. The government, which controls the importation of coke, has already limited the price of metallurgical coke to 175 fr. (normal value \$35) per ton instead of the former 275 fr. (normal value \$55) per ton. This was done in agreement with the officials of steel plants. The consequence was a drop of the prices for hematite pig iron from 850 fr. (normal value \$170) to 700 fr. (normal value \$140) per ton and a 20 per cent drop in the prices of finished steel products. This is a beginning.

FRENCH HYDRAULIC POWER

According to a very recent study made by the writer on the subject of French hydraulic power, the following data may serve to complete the succinct information given in the preceding letter (see CHEM. & MET., Oct. 20, 1920, p. 764):

Before the war the sum invested in the hydro-electric industry amounted to over a billion francs (normal value \$200,000,000). It was estimated that the investments were apportioned as follows: 525,000,000 fr. (\$105,000,000) for power and light; 100,000,000 fr. (\$20,000,000) for electrochemical and electrometallurgical industries; 75,000,000 fr. (\$15,000,000) for electric railways; 300,000,000 fr. (\$60,000,000) for sundry small industries.

Taking as an average 800 fr. (\$160), the pre-war installation cost per horsepower, it would follow that up to 1914 there was installed in all France about 1,250,000 hydro-electric horsepower.

During the war France made great strides for further hydro-electric development, and from 1914 to 1918 500,000 more horsepower was installed at a cost about double the pre-war cost, so that at present there are in operation hydro-electric power plants installed at an estimated total cost of 2,000,000,000 fr. (\$400,000,000).

A government commission is now studying the

development of all the French waterfalls not yet used and which are estimated to represent 10,000,000 horsepower. Projects are under way for the installation of plants aggregating 3,000,000 horsepower. This installation will enable France to make important coal economy. (There is under way a project for electrifying 8,000 km. [about 5,000 miles] of railroad, which if realized would result in an annual economy of 3,000,000 tons of coal.) It is estimated that the cost of reclaiming the 3,000,000 horsepower would amount to about 4,000,000,000 fr. (\$800,000,000), and could be finished within fifteen years. It is expected that the report of the commission will soon be presented to the French Parliament.

To the above-estimated 10,000,000 hydro-electric horsepower available in France may be added about 400,000 horsepower which could be obtained by using the Rhine falls between Basel and Strassburg as provided in the Versailles treaty. But to reclaim this power it would be necessary to build a canal entirely situated on French soil.

Although this would open direct water communication from Basel to the sea for ships up to 1,200-ton size, the Swiss Government is strongly opposed to the plan and bases its contention on the Oct. 17, 1868, treaty of Mannheim guaranteeing the free navigation of the Rhine. The Swiss ask that instead of a French canal the bed of the Rhine between Basel and Strassburg shall be rendered navigable. It is quite evident that England will back up the Swiss contention.

FRENCH CHEMICAL ENTERPRISES

Due to the depreciation of money, the French chemical enterprises have been forced to increase their capital stock. Thus the Société de Saint-Gobain has increased its capital stock from 60,000,000 fr. (\$12,000,000) to 120,000,000 fr. (\$24,000,000). This society, founded during the seventeenth century, although quite conservative in its technical processes, is commercially well managed and is one of the strongest mineral chemical enterprises. It has a number of plants in France, a branch installation in Mannheim on the Rhine and is now planning to build a new plant in Strassburg.

The Société de Saint-Gobain has recently become financially interested in the Claude process of synthetic ammonia and contributed to the increase of capital of the society of L'Air Liquide, a company working Claude's processes. If the rumors are right the Saint-Gobain society would absorb entirely the company L'Air Liquide and start on a big scale the manufacture of synthetic ammonia by the Claude process.

During the last month the daily production of synthetic ammonia in Claude's experimental plant has increased tenfold, now producing 1.5 tons per day. It is the Saint-Gobain company's intention to bring up the production to compare favorably with the German 1,000-ton-per-day production by the Haber process.

The Etablissements Kuhlmann has also increased its capital stock to 80,000,000 fr. (\$16,000,000). This company grew rapidly during the war. Like the Saint-Gobain company, it manufactures mainly mineral chemicals and has also started in the synthetic ammonia industry, but using the Haber process, which has been bought by the French Government for 50,000,000 fr. (\$10,000,000).

The development of these two rival branches will have a great influence on the French synthetic ammonia industry.

Pure Metallic Arsenic

Occurrence—Description of Process in Plant of the Hoskins Process Development Co. of Chicago, Which Produces a Quantity of Metal Equal to the Requirements of the United States—Properties of the Metal—Crystalline Structure—Uses in Metallurgy

BY CHESTER H. JONES

THE term "arsenic" in commerce is usually misapplied to the trioxide (As_2O_3) instead of the elementary or metallic arsenic which exists at ordinary temperatures. It is with the latter substance this article attempts to deal. Previous to the late unpleasantness there was an importation of the metal to the United States of about 50,000 lb. (22,720 kg.) per year, principally from Germany, where it had been distilled direct from arsenical ores. Subsequently the production has been developed in a Chicago plant to meet the present demand in this country. The raw material for this plant is the arsenic trioxide, or white arsenic, a byproduct from metallurgical operations at various American smelters.

While metallic arsenic is found in the natural state

FIG. 1 ARSENIC REDUCTION FURNACES

in some districts, it more commonly occurs in ores in combination with other elements such as:

- Cobaltite, $CoAsS$.
- Mispickel, $FeAsS$.
- Smaltite, $CoAs_2$.
- Mimetite, $3Pb_3As_2O_{11} \cdot PbCl$.
- Nickel glance, $NiAsS$.
- Orpiment, As_2S_3 .
- Realgar, AsS .
- Scorodite, $FeO_3 \cdot As_2O_3 \cdot 4H_2O$.
- Sperryllite, $PtAs_2$.

Most of these minerals are found in varying quantities in the gold, silver, lead, copper and zinc ores, particularly in our Western mining districts.

Investigations in connection with proposed legislation against smelter fumes in these localities led to belief that the arsenic vapor contained in the fumes issuing from the stacks was largely responsible for the destruction of vegetation and injury to animal life. The operating companies have consequently been forced to recover the arsenic in Cottrell precipitators and bag houses, and on subsequent refining by sublimation have recovered arsenic trioxide. The trioxide obtained from

FIG. 2 CHARGING END OF FURNACE

these smelters and plants roasting high-content arsenic ores gives the supply of raw material for the operations described in the following paragraphs.

HOSKINS PROCESS DEVELOPMENT CO. PLANT

The one plant in the United States making metallic arsenic of a guaranteed purity over 99.5 per cent is located in the west side manufacturing district of Chicago. Fig. 1 shows the battery of four reduction furnaces, one large and three smaller, having a total capacity of 250 to 300 lb. of metal per day.

The charge with proportions consisting of about 1 lb. of wood charcoal to 4 lb. of arsenic trioxide is placed in a rotary mixer. The mixed batch for charging to the small furnace weighs about 200 lb. and for the large furnace about 450 lb. Fig. 2 shows the charging end of the large furnace in operation.

In Fig. 2 the gas flame may be seen beneath the

FIG. 3. RIGHT SIDE OF FURNACE

retort and the pyrometer leads coming from the cover. All four furnaces are equipped with pyrometers using nickel-chromium couples and connected through a multiple switchboard to give temperature reading on each furnace. The temperature varies between 1,200 and 1,300 deg. F. (650 and 700 deg. C.).

The reaction in the furnace is

These furnaces are built of large steel pipe surrounded by No. 1 firebrick held in place by riveted steel plates, all supported on pipe framework. Fig. 3 shows the arrangement of gas piping. The water-cooling supply for the charging end cover is conducted through the smaller pipe. This cover is clamped against a clay gasket in which is buried a 1-in. copper pipe filled with the cooling water. In case of any leak of the arsenic fume it condenses against the cooled surface, rendering the joint tight.

The water supply for both the condenser appearing at the rear end of furnace in Fig. 4 and for the gasket cooling-coil mentioned in the foregoing paragraph consists of a 3-in. stream running continuously from the city mains.

The period of operation for the large furnace occupies about ten hours and for a small furnace seven hours. Running under normal conditions the plant produces not

FIG. 4. LEFT SIDE OF FURNACE

less than 4,000 lb. of metallic arsenic of 99.5 to 99.9 per cent purity per month. The small impure fraction consists chiefly of arsenic trioxide.

Fig. 5 shows the rear end of the battery with pans containing the lumps of metal immediately beneath the point of removal. When the run is finished and the furnace has been allowed to cool, the cover clamps are removed, permitting the cover to be taken off. The crystalline metal which has been formed in the tee, by carefully controlling the temperature and pressure during the heat, is taken out with bar and hammer. It is then ready for barreling and shipment.

A feature of safety to prevent poisoning of the operators is the ventilating arrangement and exhaust fan. Two of the small hoods connected to the system are shown just above the discharge end. The operators wear woolen masks over the nose to avoid injury from

FIG. 5. DISCHARGE ENDS OF FURNACES

the fumes or dust. With these precautions the danger from poisoning is negligible. There are many features of this process which have required a period of several years before the ultimate production in the commercial plant described.

PROPERTIES OF ARSENIC

Metallic arsenic (As , molecular weight 300) is classified with nitrogen, phosphorus and antimony in the periodic system. It is chemically analogous to phosphorus, but is more metallic in character. As a metal it behaves like sulphur. Thus the sulphides and arsenides have similar formulas, are isomorphous, and in them sulphur and arsenic can mutually replace each other in atomic ratios—e.g., FeS , FeAs , and FeSAs .

The characteristics of the three metallic varieties when condensed in a glass tube from distillation of arsine in the laboratory are well known. Nearest the flame the crystals form, further on the shining mirror and finally the amorphous. The last is microcrystalline, probably isometric, and black with little luster. It has a specific gravity of 4.71 and when heated to 360 deg. C. out of contact with air sets heat free and reverts to the larger crystalline variety.

The vapor density of metallic arsenic corresponds to the molecular weight, As_2 ($= 300$), with the lemon yellow vapor at 450 deg. C. At white heat, about 1,700 deg. C., the density falls to one-half, or As , ($= 150$), showing the diatomic molecule.

The crystallized variety, which is the normal product of these furnaces, so far as has been investigated, varies from the hexagonal to acute rhombic octahedra. It has a specific gravity of 5.73, is brittle and may be pulverized without difficulty. The hardness is 3.5 (Mohs

FIG. 6. METALLIC ARSENIC CRYSTALS (SLIGHTLY REDUCED)

scale); the luster is tin-white metallic, tarnishing to black by oxidation in moist air at ordinary temperature and gives a tin-white streak. The cleavage is perfect basal, the fracture granular.

Figs. 6 and 7 show crystals taken at random from the run of furnace and indicate plainly the clean nature of the commercial product. Arsenic in metallurgical classification lies between the true metal and the non-metal. It behaves in certain ways like the one and in other ways like the other. It will form alloys in some cases and is thrown out of the molten mass or forms "speiss" with others. Although a metalloid, it is a good conductor of heat and electricity.

USES

The metal acts in the nature of a flux for other metals, promoting the union of metals which would otherwise be difficult to mix. The trioxide cannot be successfully substituted for the metallic arsenic in the work. Arsenic bronze, now used for railroad brasses, is a good example. (Composition: Copper 80, tin 10, lead 10, arsenic 8.) The structure remains unchanged, but there is a gain in crushing strength and a lower temperature is required to crystallize. A content of 0.65 metallic arsenic increases the resistance to hammering.

The arsenic may be added directly to the molten metal, or a rich alloy of arsenic with copper or lead may be made and proper proportions of it used.

It seems to be the consensus that a small percentage of arsenic added to copper to be used in sheets, tubes,

Arsenical lead contains about 2 per cent arsenic. The product is harder, but the more important property of increased mobility of shot when molten is secured. This results in a more uniform output from the shot tower.

Metallic arsenic is also used in the manufacture of speculum metal for mirrors in large telescopes.

CONCLUSION

We have, then, a process and plant perfected by American chemists producing on a commercial scale an element of guaranteed purity and known to be useful in the improving of a few of our metals for important uses. But the field is scarcely touched as yet, the research is only in the preliminary stages, and we may venture to hope for much in future developments. To have at hand a pure metal, to find these new things it will do with other pure metals, its behavior in many eutectic mixtures, and all its meanderings through the wide field of chemistry with ultimate benefit to industry at large—this is a thing worth while.

We are indebted to the Hoskins Process Development Co. for the material contained in this article.

staybolts, etc., for locomotive fireboxes will increase the tensile strength, rigidity, hardness and resistance to action of gases as compared to pure copper. Added to copper for castings it reduces blow-holes and increases fluidity. Copper to be drawn into wire works better in the drawing process and the melting point and conductivity are lowered.

The annealing point of copper is raised by the addition of arsenic, and a tougher metal results. The injurious effect of small quantities of bismuth is counteracted. Arsenic tends to deoxidize the copper.

A higher percentage of lead may be carried in a zinc alloy by the addition of metallic arsenic.

When added to brass for casting up to 0.5 per cent, it increases the fluidity when molten, gives sharper and cleaner castings and increases the strength and elongation. It increases the ductility of Muntz metal (60 copper, 40 zinc).

A finer grain and increased hardness is secured by adding metallic arsenic to white bearing metals.

The Indian Mica Industry

MICA is one of the things, like jute, for which for certain purposes no satisfactory substitute has been discovered, and although it is not, like jute, an Indian monopoly, more than half the world's supply of the mineral comes from that country. In India it is very widely distributed, but the tracts in which it is found in plates of sufficient size to have a marketable value are few and strictly defined. Mica in more recent years has been mined in the Nellore district of Madras, but the main deposit is in a belt about eighty miles long and twelve broad, which lies in the northern part of the Hazaribagh district and stretches into the adjoining districts of Gaya and Monghyr. The main center of the industry is at Koderma, in the Hazaribagh district.

PRIMITIVE METHODS OF MINING

Mica does not occur in thick seams like coal, but in small deposits or "books," and a mica mine or quarry presents the appearance of a huge rabbit warren, the workers burrowing from "book" to "book" by passages that are sometimes just sufficient to admit a small boy. In most cases very primitive methods are used, the lower levels of the mine being reached by roughly made bamboo ladders and the excavated material being passed, hand over hand, from one coolie to another. The bailing out of water is done in the same way by the use of buckets, and during three months in the monsoon operations may be suspended altogether, the mica being under water. In one of the mica districts, before the war, a German firm was the only one of the many agencies at work that employed a steam pump. As the demand for the mineral has increased and the deposits near the surface have been worked out, more scientific methods

for extracting the mineral are gradually being introduced, and mica is now being dug by means of shafts 300 to 400 ft. deep.

USE OF MICA IN THE ARTS AND MEDICINE

Mica has been extensively used in the native arts of India from time immemorial. The powdered mica is used in calico printing and by washermen to give a sparkle to cloth. It is a substitute for glass in lanterns, and the material out of which "unbreakable" lamp chimneys are manufactured. It fills the peepholes of furnaces, and is used for windows in cases where glass would break on being exposed to extremes of heat or to concussion. It is a glazing material for pottery, for pictures, and for the backs of mirrors. Indian artists have used it largely for paintings.

Mica also has a high reputation in Indian medicine. It is used as a finely ground powder, either by itself or in combination with other drugs; it is said to be a tonic. Indian medicine classifies nearly all drugs and articles of diet into two groups—the "heating" and the "cooling"—and mica is said to be the most efficacious of all the drugs in the latter class. It is said that some Indian practitioners have a secret means of dissolving mica, but this is doubtful. Such solvent would be a great discovery, for it would mean that mica could be used for the manufacture of unbreakable tumblers and decanters.

A NON-CONDUCTOR OF HEAT AND ELECTRICITY

"Mica paste" or "mica grease" is used as a lubricant and to plaster on boilers to diminish the loss of heat, for mica is a non-conductor of heat. It is believed to be the chief constituent of the preparations that are used for painting the under side of iron roofs to promote coolness and for other similar purposes, and it has been recommended, and actually used, as a lining for sun helmets.

The main importance of mica in modern industry, however, lies in the fact that it is one of the best non-conductors of electricity and is, therefore, indispensable in electrical engineering. On this account the government took over part of the mica field during the war and worked it as a state industry in order to make sure of having a constant supply.

"MICANITE"

Impetus was given to the industry about twenty years ago by the invention of a method of cementing small pieces of mica together and molding them into sheets, which are called "micanite." In former days it was said that 80 per cent of the mica which was dug out of the mines was waste, and great waste dumps of the refuse, glittering in the sun, were a conspicuous feature of the mica mines and factories where the splitting was done. Since this process of welding was introduced a considerable amount of marketable mica has been recovered from the waste heaps, and the process also permits the use of a larger proportion of the mineral that is excavated.

UNSKILLED LABOR EMPLOYED

The industry gives work to a large number of unskilled laborers. Even the work in the factories, where the thick pieces are split into thin sheets and cut to the proper sizes, is easily learned by women and children, and a daily wage can be earned that is considerably in excess of what is paid for field work.

PLANT OF THE HOOKER ELECTROCHEMICAL CO., NIAGARA FALLS

Chemical Efficiency and Concentration of Caustic and Salt From Townsend Cells*

Brief Description of the Townsend Cell Installation of the Hooker Electrochemical Co.—Some Characteristic Properties of Saturated Cathode Liquors—Concentrations and Equilibriums of NaCl-NaOH Solutions—Chemical Efficiency

By ALBERT H. HOOKER

DR. BAEKELAND in 1907 described the general principles of the Townsend cell and process of operation in the *Journal of the Society of Chemical Industry* and *Electrochemical and Metallurgical Industry*.¹ Since that time there has been a large development in the production of chlorine from these cells and some material modifications in design and operation have taken place. For that reason it seemed proper to bring before this symposium on electrolytic cells a brief description of the plant of the Hooker Electrochemical Co. at Niagara Falls, where we are producing about sixty-five tons of caustic soda and sixty tons of chlorine daily from Townsend cells.

*Read before the American Institute of Chemical Engineers, Montreal, June 28, 1920.

¹Now CHEM. & MET. ENG.

The heading of this article gives a general view of the plant covering about thirty-eight acres. In the left foreground will be seen the research laboratory; behind that the chlorbenzol plant, where about thirty tons a day of chlorbenzol was made during the war for the French Government to convert into dinitrophenol to modify its picric acid explosive; near that will be seen the plant for the manufacture of a very pure grade of muriatic acid, practically water white. The two larger buildings are the boiler plant, with a modern equipment of mechanically stoked boilers used to supply heat and steam for evaporation and process work, and one of the evaporation houses containing vacuum pans and pots for finishing caustic. The two power houses, five cell buildings, bleach chambers, brine purification tanks, machine and repair shops, office building, general labo-

CHART 1. SPGR. AND GRAM/LITER OF SAT. NaCl-NaOH SOLUTIONS

ratories, liquid chlorine and synthetic chemical units form the general group to the right of the picture, while in the distance can be seen the plant where we made picric acid for the Government from monochlorobenzol during the war.

TYPES OF TOWNSEND CELLS

This work all centers around the production and use of chlorine and caustic soda from the Townsend cells.

The power is received from the Niagara Falls Power Co. as three-phase, alternating current at 12,000 volts, and after passing through transformers and rotary converters is delivered to the cell circuits at about 260 volts and 4,000 to 5,000 amp. direct current.

We have several types of Townsend cells in operation, a small circuit of the original 2,500-amp. cell and some of the earlier 5,000-amp. cells. However, Fig. 1 shows

one of our more recent cell bays, which consists entirely of 4,000-amp. cells. In the building there are 120 cells, each with a daily output of slightly over 300 lb. of caustic soda, or a total of eighteen tons. Fig. 2 is a more detailed view of one of these cells, which is of the long, low type of large capacity.

We find it expedient at Niagara Falls, with existing power costs, to run at exceptionally high current densities, about 100 amp. per sq.ft. of cathode, and hence use a little over four volts per cell during an average run, and an ampere or current efficiency of between 96 and 97 per cent. Owing to the circulating system which we use to maintain saturation, as well as the novel use of oil in the cathode compartment, we are able to obtain this efficiency with a caustic strength considerably above 125 g. NaOH per liter.

Another interesting group of cells is the corrugated type of low cell. The previous design was intended to give the maximum horizontal surface of cathode consistent with a large unit and the simplicity of the straight side plates. The cell was designed to crimp this plate accordion fashion and thus permit a much greater horizontal surface for the escape of gas within the same ground area. This was intended to reduce materially the voltage of the cell at the same current density.

In this bay of 5,000-amp. cells the result of lower voltage is fully accomplished and a natural saving is made in the cost of both installation and power. The design still requires some perfecting to work out a perfect diaphragm control and simplicity of renewal repairs. Consequently, while power costs are low, the chemical efficiency is not quite as good—say 93 or 94 per cent.

When it comes to a final monthly balance sheet with

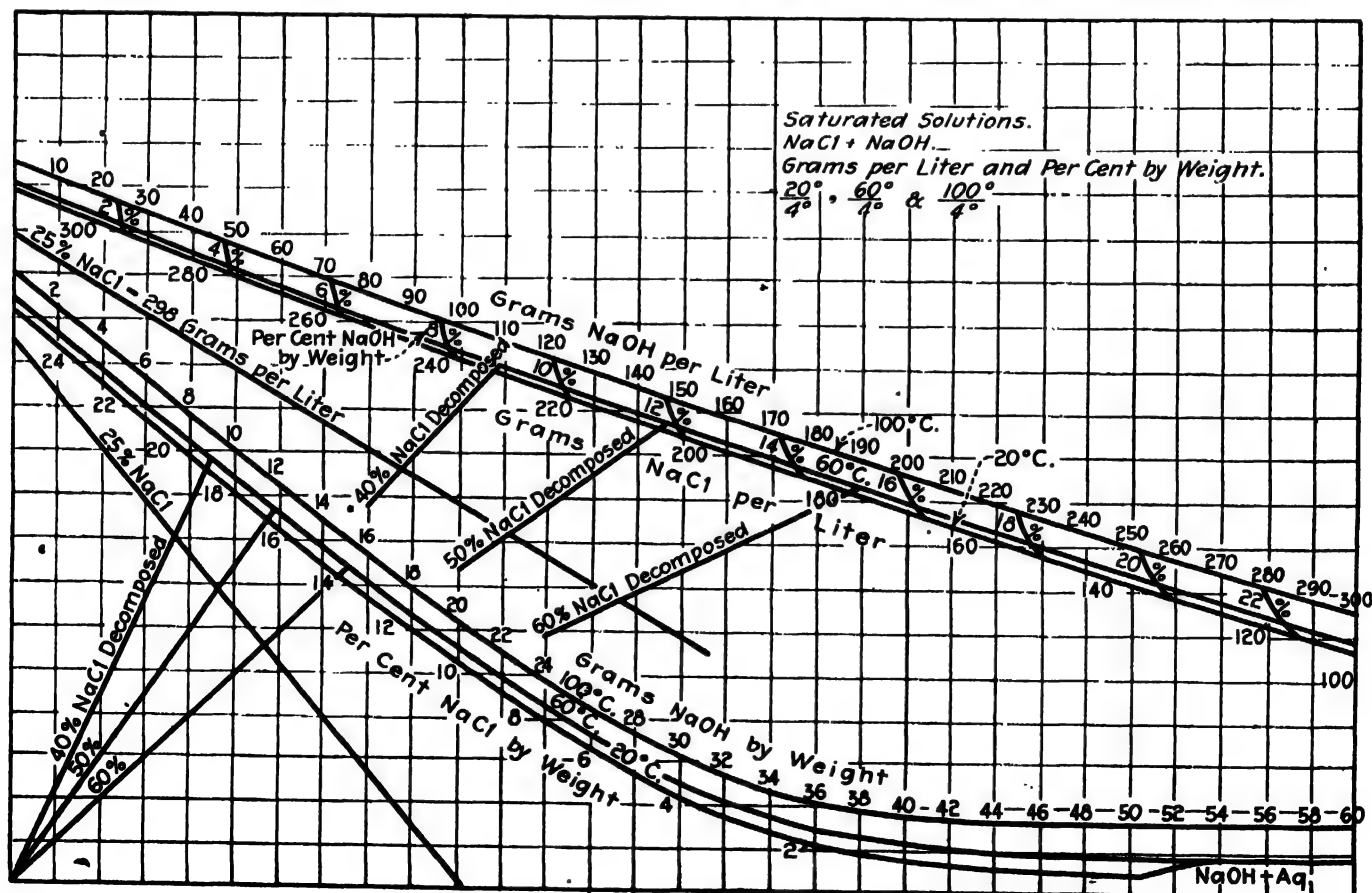

CHART 2. PER CENT BY WT. AND GRAM/LITER SAT. NaCl-NaOH SOLUTIONS

Niagara Power costs the two groups run a very close commercial race, but there are other locations where a choice might clearly point to either one of the two types as the better.

A study of the cathode liquors from these different types of cells has led to some interesting results, which it is my hope to bring out in the paper which follows.

CATHODE LIQUOR DATA

Solutions saturated with NaOH and NaCl at various temperatures form the products which we are constantly handling in dealing with cathode effluent from diaphragm cells used in the production of caustic soda. Winteler has given a very full table showing the grams per liter of NaOH and NaCl as well as specific gravity of the solutions saturated at 20 deg. C. This table has been very freely used and is found in most of the literature, English, German and French, dealing with this subject. Engel has given a more limited series of observations not so generally used and based on determinations at zero and 15 deg. C.

I had occasion in 1911 or thereabout to use the figures of Winteler reduced to per cent by weight by use of his specific gravity determinations, and from these figures very slightly modified prepared a number of rather complete saturation curves. Some of these I had intended to use in this paper. However, experience has clearly shown that there were some material errors, particularly in the specific gravity determinations of Winteler. I have, therefore, re-determined many of these figures and submit new figures which I hope with your criticisms and corrections may form a substantial basis for future calculation. I might add that Winteler's figures considered only as grams NaOH and NaCl per liter agree closely to my own observations over the important range of the curve. The specific figures offer the serious difficulty. Engel's figures, in general, agree much more closely in all regards, although the range is more limited. Chart 1 shows the essential differences and corrections which I have made and use in subsequent charts. Chart 2 shows both per cent by weight

CHART 1. SPECIFIC GRAVITIES OF NaOH AND NaCl-NaOH SOLUTIONS

and grams per liter of saturated solutions of NaOH and NaCl at 20/4 deg., 60/4 deg., 100/4 deg. Chart 3 shows the corresponding specific gravities for these solutions. Chart 4 shows specific gravity 20/4 deg., 60/4 deg., 100/4 deg. for pure NaOH solutions, and, incidentally, for saturated NaOH and NaCl solutions at 20 deg. C. This chart I have purposely ruled to bring out one feature which I found was not generally considered by our chemists in preparing curves and which I find quite useful. If a sheet of cross-section paper is prepared showing grams per liter on the lower margin and specific gravity on the side margin, say with a range in specific gravity from 1.000 to 1.500, obviously a line ruled from 100 g. per liter at 1.000 specific gravity connecting 150 g. per liter at 1.500 specific gravity will represent a 10 per cent solution by weight at any intermediate specific gravity. A corresponding line from 120 g. per liter at 1.000 specific gravity to 180 g. per liter at 1.500 specific gravity will represent a 12 per cent solution by weight at any intermediate specific gravity and to paper ruled in this way can be transferred figures either in per cent by weight or grams per liter at will, and both readings can be made from the same

CHART 2. SPECIFIC GRAVITIES AT 20 DEG., 60 DEG. AND 100 DEG. C. OF NaCl-NaOH SOLUTIONS

chart. These figures for pure NaOH solutions at 20 deg. agree closely with Lunge's tables at 15 deg. with the necessary temperature correction. However, Lunge has published an extensive table showing the change in specific gravity with temperature. I cannot make my own observations agree with Lunge's as to change in specific gravity with temperature, hence offer these figures at 60 and 100 deg. for criticism and, I believe, correction of Lunge's figures. Chart 5 gives the specific gravity and per cent by weight and grams NaCl per liter over a full range from 20 to 100 deg. C. Chart 6 shows the solubility of chlorine in water and in brine of various strengths and a full range of tem-

peratures. Also the solubility in grams of chlorine per liter and the corresponding grams NaOH which would be converted by this chlorine into hypochlorite in the cathode compartment of a cell. These first six charts are presented as the basis for those which are to follow.

ECONOMICAL SALT DECOMPOSITION

If we consider in rather simple terms the reaction which takes place on electrolyzing salt in a diaphragm cell we can express it after the sodium has decomposed water to form hydrogen by the formula

In ordinary operations there is a certain ratio of salt decomposition which offers the greatest economy for a

CHART 5. SPECIFIC GRAVITIES OF NaCl SOLUTIONS

given cell—giving due consideration to the cost of power, coal, renewals, etc. This range is usually between 40 and 60 per cent salt decomposition. Assuming for consideration an intermediate figure of 50 per cent and the use of 25 per cent brine by weight, also a formula which will express the brine depletion in the anode compartment without resorting to transport numbers, we have the following:

117 351 90 40 58.5 333 35.5 1 90
292.5 877.5 225 100 146.25 832.5 88.75 2.5 225

FEED BRINE

292.5 NaCl = 25 per cent by weight
877.5 H₂O = 75 per cent by weight

1170.0 = 981 c.c. = 298 g. per liter

CATHODE NaOH

100 NaOH = 9.27 per cent by weight 111.8 g. per liter
146.25 NaCl = 13.56 per cent by weight
832.5 H₂O = 77.17 per cent by weight

1078.75 = 894 c.c.

ANODE BRINE WITHIN THE CELL

292.5 NaCl = 20.96 per cent by weight
1102.5 H₂O = 79.04 per cent by weight

1395.0 = 243 g. per liter

We can entirely disregard efficiency in this formula and express the result in terms of product, and efficiency as the time or amperes needed to produce 100 g. NaOH.

WATER AND SALT CONTENT OF CATHODE LIQUOR

Turning now to chart 7 we have charted the results of 20, 25 and 26 per cent solutions of NaCl by weight at any rate of decomposition in terms of H₂O and NaCl per 1,000 NaOH, which represent the simplest values for a direct commercial valuation of cathode liquors in terms of coal or evaporation costs.

Next on this same chart from our previous saturation curves are plotted saturated solutions of NaCl + NaOH

at 20, 60 and 100 deg. Now, it is well known that the Townsend cell as operated at our Niagara Falls plant uses an extensive circulating system both to remove impurities in the brine and therefore increase the life and efficiency of the diaphragm and to maintain the desired degree of saturation within the cell at all times. We can thus obtain a cathode solution that is fully saturated at 20 deg. In fact, with a temperature of 60 deg. within the cell we can readily exceed this point, but care must be taken not to do this except to a slight degree, otherwise trouble results from salt deposits at various points.

Turning now to our chart we find the following results:

50 per cent decomposition
25 per cent brine
1,000 NaOH
1,462.5 NaCl
8,325 H₂O

50 per cent decomposition
Brine circulated and saturated
1,000 NaOH
1,462.5 NaCl
6,250 H₂O

This difference then is 2,075 lb. water per 1,000 lb. NaOH produced. Nor is this the only difference. We have seen that there was required 981 c.c. of 25 per cent brine to supply 292.5 g. of salt for 100 g. NaOH. In the original equation with the saturating system only 750 c.c. of brine would be supplied; the remaining salt would be added in the solid state to the saturating vault to be dissolved in the slightly depleted anode circulation.

EFFECT OF DISSOLVED CHLORINE

Now turning to our chart relative to the solubility of chlorine in brine we find that 1,000 c.c. of 21 per cent brine will dissolve 280 c.c. chlorine (760 mm.) = 0.8876 g. This, in turn, corresponds to 1 g. NaOH. Hence 981 c.c. would carry chlorine = 0.981 g. NaOH to the cathode compartment, thus reducing the product or efficiency by practically 1 per cent (the greater the feed of brine—viz., the lower the decomposition with a given brine—the greater the loss). Also 1,000 c.c. 25 per cent brine will dissolve 170 c.c. chlorine at 60 deg. = 0.539 g. = 0.60 g. NaOH; hence 750 c.c. = 0.45 g. lost NaOH = 0.45 per cent drop in efficiency; hence we are better off by fully $\frac{1}{3}$ per cent in efficiency by maintaining saturation. These chlorine losses are also shown on chart 7 relative to efficiency.

CHEMICAL EFFICIENCY

There is another and much more vital factor in efficiency that this form of chart, which I believe is

CHART 6. SOLUBILITY OF CHLORINE IN BRINE AND WATER

rather unique, permits of bringing out, and which permits of a very rational comparison of different cell performances—a study of diaphragm and general structural difficulties.

Taking all these factors into consideration our curves indicate an ideal efficiency of, say, 95 per cent with 60 per cent decomposition (a result I never have obtained), 97-97.5 per cent at 50 per cent decomposition and 97.5-98 per cent at 40 per cent decomposition. The intermediate curves point to commercial results of various

If we assume that for 100 g. of NaOH produced in unit time we feed 292.5 g. of NaCl—146.25 g. are decomposed and 146.25 g. remain with the effluent caustic at 50 per cent decomposition. This should result 97-97.5 per cent amp. efficiency according to whether we figure on a 25 per cent brine feed or saturation of the cathode caustic. Now suppose we find only 95 per cent amp. efficiency corresponding to 60 per cent decomposition, or 97.5 lb. NaCl per 100 NaOH; this means that $146.25 - 97.5 = 48.75$ NaCl per 100 NaOH has passed through the diaphragm to the cathode caustic performing no really useful purpose. This would mean 194 lb. of 25 per cent excess brine to handle for every 100 lb. NaOH produced. There are many commercial cases far worse than this that could be cited. Probably no original diaphragm is at its best until a true "Schmutz Decke," as the water filtration people say, is formed,

*0 per cent decomposition $40/60 = c_1/c_2 = 2/3$ $(2/3)^2 = 4/9$. Hence 95.6 per cent chemical efficiency.

CHART 8. CONCENTRATION OF NaCl IN NaOH SOLUTION

and certainly it makes a material difference whether there is a varied flow and consequently varied decomposition at different heights of the same cell. I offer these provisional curves as a new basis for study in cell efficiency and performance.

Another useful function of chart 7 will, I think, appeal to Hugh K. Moore. I refer particularly to its use in connection with caustic evaporator problems such as he so ably described at the St. Louis meeting in 1917. This chart permits of following directly any caustic solution at any temperature from start to finish through the vacuum pans if we start with the product of 50 per cent decomposition and 25 per cent brine having a composition of 1,000 NaOH, 1,462 NaCl, 8,325 H₂O. We concentrate until we reach 1,000 NaOH, 1,462 NaCl, 5,600 H₂O—loss 2,725 lb. H₂O—before any salt separates out. After this there is a constant removal of salt and water in the proportion of about 2,800 lb. water per 1,000 lb. salt until we reach about 30 per cent NaOH by weight. Here the rate of salt to water changes, although we now have only 200 lb. salt left from our original 1,462 lb. per 1,000 NaOH.

DATA ON CONCENTRATED CATHODE LIQUOR

At about 50 per cent concentration we have approximately 60 lb. salt left for 1,000 NaOH and this cannot be materially reduced (as will be seen by the abrupt turn of the curve) by further concentration in the evaporators. However, commercial grades of finished caustic require a material reduction beyond this point. A glance at the curve shows that nearly two-thirds of the salt present at this stage at 100 deg. can be removed by cooling to 20 deg. As this is a somewhat critical operation, it becomes desirable to magnify the small fraction of our curve between 40 per cent NaOH and 60

per cent NaOH. I prepared an interesting curve on this order in 1911. I believe Mr. Barton of the Berlin Mills has a copy which I gave him. I am not sure that any other copies were given out. I know that Mr. Mantius of the Zarembo Co. used one of our copies on our work. This chart was quite complete, as you will see by the blueprint which I am circulating, and contained, in addition to the figures on chart 9 which I am showing, the resulting analysis from finishing certain grades of caustic liquor. I have purposely left these figures from the present chart, which is materially corrected to correspond to more recent results which have gradually accumulated showing some variation from the original. While it is true that lines can be introduced showing the finished grade, these will depend upon individual plant practice, partly as regards sulphate and carbonate, but particularly as to chlorate in the final liquors, hence are not constant. The figures for viscosity I prefer to use, not as I did on the old chart, but in a final chart which I will introduce.

RELATIVE PERCENTAGES OF CAUSTIC AND SALT

This chart 9 shows per cent NaOH by weight and per cent NaCl by weight, also specific gravity and pounds water per pound NaCl. It should be borne in mind that in cooling a saturated solution of salt and caustic the caustic water ratio remains constant while the salt ratio varies. Hence if we start at, say, 100 deg. with 1,000 NaOH, or 51 per cent NaOH, 900 H₂O, and 3.1 per cent NaCl, and cool to, say, 40 deg. we will still have 1,000 NaOH, but with 52 per cent NaOH, 900 H₂O and 1.18 per cent NaCl.

While this chart gives all the necessary information, I much prefer to use this information in the form shown in chart 8, which, I believe, is quite original in

its arrangement, yet makes a most convenient form for arriving at the desired results in finishing caustic. If we start with a 51 per cent solution of caustic, this at 100 deg. will have a specific gravity of 1.503 and 1,000 lb. NaOH, 900 lb. H₂O, 62 lb. NaCl; cooling to 40 deg. C., we have practically 52 per cent caustic by weight, 1,000 lb. NaOH, 900 lb. H₂O, 22 lb. NaCl, specific gravity 1.550.

Our viscosity, which plays a very important part in the final time of settling of salt, is now practically 200 compared to water as 100. By still further cooling to 25 deg. C. we have a specific gravity of 1.560, a solution containing 1,000 NaOH, 900 H₂O, 18 NaCl, but our viscosity has reached nearly 400, making it practically impossible to settle out this last 4 lb. of salt. Also we are at the point of freezing or solidification for part of our solution, hence have passed the limits with this particular solution.

It is quite obvious that clear across this chart with 20 to 25 or 30 lb. of salt the same grade of finished caustic will result and could be plotted out. To this salt must be added the salt from decomposing chlorates, which varies with different plant operations. We have now passed from a cell liquor containing 1,000 lb. NaOH, 8,325 lb. H₂O, 1,462 lb. NaCl, to a solution containing 1,000 NaOH, 900 H₂O, 22 NaCl, and I think can safely leave the final finishing in the pots for another story.

Production of Leather From Rabbit Skins

Consul Norton writes from Sydney, Australia, that a secret process, said to be unknown hitherto to the tannery trade, has been discovered by an Australian for making leather from rabbit skins and recovering the fur as a byproduct for felt making. A company has been formed in Sydney to turn this discovery to practical use, having established works capable of handling about 100,000 skins a week. The leather has already been utilized in Sydney in the manufacture of boot and shoe uppers, hand bags, gloves and other articles.

Sugar Production in Mauritius

One of the unusual results of the recent situation in the American sugar market is the bringing of cane sugar to the United States from the small British island of Mauritius, off the east coast of Africa, says *Commerce Monthly*.

The share of Mauritius in the total sugar supply is not large, as the usual crop averages less than 2 per cent of the world's annual production. The output of about 240,000 metric tons annually represents the product of a highly concentrated industry carried on in one of the most densely populated regions of the world. With an area of 720 square miles, less than one-sixtieth of that of Cuba, the island devotes 176,000 acres to sugar plantations, or about one-eighth of the acreage in Cuba, recently reported as 1,385,000. The sugar crop of Mauritius for the past three years has averaged about

TABLE I. PRODUCTION OF SUGAR IN MAURITIUS
(In thousands of metric tons)

Year	1912-13	1913-14	1914-15	1915-16	1916-17
Production	213	250	277	215	209
Imports	1917 18 ...	1918 19 ...	1919 20 ...	1920 21 ...	* Estim.
	226	23	235	40	

6 per cent of the Cuban crop. Production for the years from 1913 to date is shown in Table I.

Practically the entire crop is exported, as less than 10,000 tons a year is reserved for local consumption. As a rule the value of the sugar exported is more than sufficient to pay for the total imports received. Sugar accounts for 90 to 95 per cent of the exports, and molasses and rum are relatively large items in the balance.

During the war and the two following years the British Royal Commission on the Sugar Supply purchased the bulk of the Mauritius sugar and it is stated that the quantity contracted for in 1920 amounts to 200,000 tons.

TABLE II. SUGAR TRADE OF MAURITIUS
(In thousands of metric tons)

Year	Total Exports	Imports Into United Kingdom	Imports Into British India
1909-13 (average)	205	38	139
1914	209	71	145
1915	226	195	87
1916	231	110	71
1917	191	52	26
1918	197	100	33
1919	260	181	78
1920	221	104	24

* Total exports and imports into United Kingdom are for the calendar year while imports into British India are for the year ended March 31.

† Eleven months ended July 31.

‡ Ten months ended May 14.

§ First eight months.

Total exports of sugar from Mauritius and the amounts imported into the United Kingdom and British India from 1909 to date are shown in Table II.

The industry is carried on largely by French and Indian planters, the latter cultivating as much as 40 per cent of the total area in sugar cane. A syndicate represents the interests of the planters and it may later supervise purchases of machinery and other supplies. The development of the industry in the island has reached a flourishing state. Part of the cane area is irrigated and the fifty-nine sugar estates operate light railway systems to carry cane to the mills. Modern crystallizers and centrifugals are in use and there is an active interest in labor-saving machinery. It has been suggested that American manufacturers might find a market in Mauritius for sugar mill machinery, rails and tramway supplies.

Steel Rails From Sink-Head and Ordinary Rail Ingots—II

A Detailed Statement of the Disposition of the Metal From Ingots Used in This Test, as Demanded by Its Mechanical and Chemical Characteristics—Sink-Head Ingots Are Shown to Give Much More Uniform Metal Than Common American Types*

• BY GEORGE K. BURGESS†

SINK-HEAD INGOTS

DUE to the uncertainty of the location of the sink-head junction, an arbitrary allowance has to be made in advance at hot saw or shears, or one risks having the A rails rejected. If the total top discard (bloom and rail) is adjusted to 13 per cent there will be no rails rejected on account of sink-head; if this is set at 8 per cent one would expect about one-half the A rails to contain surface imperfections caused by the sink-head and ingot junction. The sink-head alone entails on the average a discard of about 9.1 per cent of the Hadfield ingot, as is shown in Table VI.

The ingot usually enters the rolls with large end and sink-head first; there appears, however, to be no difference which end of ingot is first subjected to the "squaring up" pass. The presence of the sink-head appears to present no difficulties in either the blooming mill or rail mill. One ingot cracked at the bottom of the sink-head during rolling, but this was without effect on the passage of this bloom through the rolls.

Two of the thirty-five sink-head ingots (Nos. 18 and 4) examined as rails had pipes, detected in the mill, extending into the ingot 10 or 11 per cent, or to about 5 per cent below the sink-head in some cases (Table VI). All piping would appear to be eliminated with a discard of 11 per cent, which turns out to be very nearly that required to eliminate all sink-head imperfections and carbon segregation above 12 per cent (Table X).

COMPARISON INGOTS

As already noted, there were fifteen Maryland ingots in three groups of five each, of about 7,300 lb. each, top poured into ingot molds with small end up. They were rolled as portions of three heats on different dates, the total number of ingots in a heat being thirteen or twenty. The time of teeming into molds was about 35 sec. each and the temperatures are as shown in Table VII. The product from each heat thus forms a distinctive group and should be considered separately. The ingots were selected arbitrarily before being cast, it being agreed that five ingots would be taken and they were to be poured in succession after the second one of the heat. The heats were three of a series of rail steel from the ordinary output of the open hearth.

The first ten ingots, heats 2x4497 (ingots M1 to M5) and 1x3632 (ingots M6 to M10) were apparently made from rising steel, while ingots M1 to M15 of heat 2x4510 were from quiet or "killed" steel; ingots M6 to M15 were deoxidized with aluminum; ingots M1 to M10 were chilled on top, M1 to M5 with cast-iron caps, and M6 to M10 with water.

The effects of these differences in furnace and casting practice are very striking on the finished product. Thus the deoxidized flat-top ingots M11 to M15 show, as would be expected, pronounced piping; for this group, the average discard to physically sound steel is 26.5 per cent (Table VI) and ranging from 8.5 to 39.5 per cent. With this discard may be compared the discard of 5.2 per cent for the first Maryland group and 8.0 per cent for the second, and, except in two cases out of thirty-five, a negligible discard for piping below the sink-head of the Hadfield ingots (Table VI). The small discard (6.6 per cent) to sound steel for the average of the first two Maryland groups is, however, misleading, as there may exist internal or enclosed pipes—especially in the second or deoxidized group. In the first comparison group (ingots M1 to M5) one would ex-

FIG. 3. RAIL M1-A

Sulphur print shows extreme segregation from top of ingot.
A—Moderately fine grained hyper-eutectoid segregation, pearlite with a trace of cementite and many small slag inclusions.
B—Moderately fine grained hypo-eutectoid structure, pearlite with a thick irregular ferrite network.

*For Part I see *Chem. & Met. Eng.*, vol. 23, No. 19, Nov. 10, 1920, p. 921.

†Chief division of metallurgy, Bureau of Standards.

pect to find a spongy segregated structure in the upper part of ingot. This is brought out in some of the sulphur prints of rail from the upper part of the ingots of this group, a typical one being shown in Fig. 3.

Of the first group, M5 contains a very pronounced pipe near the bottom of the ingot in the F position (Fig. 6). The question may be raised as to whether the practice of chilling the ingot top does not tend to produce internal pipes which may be distributed anywhere along the center line of the ingot.

The phenomenon of segregation, which is intimately allied to the furnace and casting practice for the Maryland ingots, is discussed separately. The mechanical properties, as brought out by the several tests, ultimate strength, yield point, elongation, reduction of area, hardness and drop test, show less dependence on the processes of manufacture, as will be brought out later.

CHEMICAL SEGREGATION OF INGOTS OF BOTH TYPES

Each Maryland ingot furnished six and each Hadfield ingot four rails, as shown in Fig. 2.* In studying segregation in the "A" test piece it should be remembered that for the sink-head ingots this position is that of the drop test piece at about 9 per cent below the top (including sink-head), while for the comparison ingots the "A" test piece is at the junction of the "X" and "A" rails, or at 10.6 per cent from the top of ingot. They are placed in sufficiently similar position therefore for the comparison, except that 10.6 per cent of a comparison ingot (7,260 lb.) includes 770 lb. or 23 ft. of rail, while 9.6 per cent of a sink-head ingot (5,300 lb.) contains 509 lb. or only 15 ft. of rail. The "A" position in the comparison thus has an average rail discard 8 ft. greater than the sink-head ingot.

The "E" position of the rails from sink-head ingots should be compared with the "F" position of the comparison ingots, the sink-head "D" with comparison "E," the sink-head "C" with comparison "C" and "D," and the sink-head "B" with comparison "B."

*See p. 924.

Chemical Tests. Determinations were made of the amounts of carbon, sulphur, phosphorus, manganese and silicon at the "O" and "M" positions (Fig. 4) for test pieces (B, C, D, etc., of Fig. 2) of all the rails. "X" and "A" rails of the comparison ingots and "A" rails of the Hadfield ingots were broken in 5-ft. pieces and analyzed with results, the more typical of which are included in Table XIII. Some specifications contain a clause which provides for the rejection of rails when the "M" position shows a carbon content more than 12 per cent greater (positive segregation) or more than 12 per cent less (negative segregation) than the "O" position. In the present investigation all material showing more than 12 per cent positive or negative carbon segregation was considered as unavailable for rails. The railroad using this specification has found from experience that 12 per cent is the maximum safe limit of segregation.

For both types of ingot, as shown in Table VIII, the longitudinal segregation of carbon is very slight along

FIG. 4. 100-I.R. PENNSYLVANIA RAIL SECTION SHOWING LOCATION OF VARIOUS TESTS

"O" is outer position for chemical analysis.

"M" is middle position of sample for chemical analysis and tensile test.

1 to 7 represent points where hardness was measured.

the "O" or tread positions, while for the "M" (top of web) positions, or along the center line of the ingot, it is quite marked, the carbon being greatest at "A" near the top of the ingot, decreasing to the "H-D" (or "M-E") position, and rising again as the bottom of the ingot is approached. The Maryland results are tabulated for the three types of ingot, but for this effect the type of ingot appears to play less of a role than for other factors.

The segregation of the sink-head ingots and of the three groups of ingots made with small end uppermost are discussed separately with reference to influence and method of manufacture.

TABLE XII. DISCARDS IN RAILS FROM COMPARISON INGOTS

Ingot	A-rail Crop. (Ft.)	Cut for Segregation (Ft.)	Top Discard, per Cent		Middle Discard		Total Discard	
			For Segregation	For Soundness	For Segregation	For Soundness	Chemical	Physical

* M13 and M14 contain a trace of piping in B position.

† M15 has a small pipe at F.

SEGREGATION IN SINK-HEAD INGOTS

The sink-head ingots were of "piping" steel deoxidized with aluminum. Each is from a separate heat of converter steel.

These ingots are, in general, of remarkable uniformity as regards segregation (Table IX), thus showing the furnace and casting practice also to have been very uniform. At the "A" test piece 9.1 per cent below the top of the ingot on the average, the segregation, though variable, is always positive—i.e., the carbon content of the "M" position is greater than that of the "O" position. Fourteen of thirty-five ingots have a segregation greater than 12 per cent and three greater than 25 per cent; for one of these (H13), the "A" position is only 5.1 per cent below the top of the ingot (Table VI).

For these thirty-five sink-head ingots, the discard for segregation above 12 per cent is located 13.0 per cent plus or minus 1.86 below top of ingot, with a maximum of 17.5 per cent and a minimum of 5.1 per cent (Tables VI and XI).

SEGREGATION IN COMPARISON INGOTS

Group M1 to M5, Heat 2x4497. This heat has no aluminum addition in molds, and cast-iron caps were put on the tops of the ingots as soon as poured. It was found that the ingot tops were rounded after the steel had solidified; therefore they were made of rising steel not specially deoxidized in the mold. The ingots were stripped 20 min. after casting and remained in soaking pits from 2 hr. 10 min. to 2 hr. 23 min. This is about as rapid handling of ingots in the molds as it is possible to have, although the time in pits could have been lessened. The resulting composition and segregation is strikingly characteristic of the history.

The top of the ingot is characterized by high and variable segregation; thus the total top discard required to eliminate segregation above 12 per cent ranged from 23.7 to 31.9 per cent for the five ingots, as compared with a top discard of 2.6 to 9.3 per cent to the physically sound steel—i.e., free from pipe. (Tables VI and XII.) Within this range of discard for segregation,

FIG. 5. RAIL M4-F

Sulphur print shows soft streak in web from bottom of ingot. A—Moderately fine grained structure, pearlite with a thick irregular ferrite network, and ferrite clusters. Soft streak in web of rail.

B—Average moderately fine grained structure, pearlite with a trace of ferrite.

however, the segregation in a single ingot varied by enormous amounts, such as 26.52 to 94.62 per cent for ingot M2 and —7.36 to 49.28 per cent for ingot M5 (Table XIII). This type of ingot is also characterized in all cases by high negative segregation in the lower portion of the ingot, particularly marked at the "E" position, where it ranges from —12.34 per cent to —15.89 per cent (Table X). Except for M1, at the bottom of the ingot "F" position (—13.45 per cent, Table X), there is a reversal to relatively small positive segregation. All but M2 contain a well-marked soft streak at F, the bottom of the ingot, and in the case of M5 this streak encloses a very bad pipe (Figs. 5 and 6). The total material that should be discarded from this type of ingot for segregation ranges from 58.2 to 63.9 per cent (Table XII). Provision should be made for a larger bottom bloom crop than is customary, to eliminate both segregation and piping in the bottom of the ingot. The bottom rail and the one next the bottom of every ingot of this group (M1 to M5) should be discarded for segregation, and the bottom rail has in addition elements of physical weakness shown by the soft steel streaks which may enclose pipes.

Group M6 to M10, Heat 1x3632. The ingots of this heat had rounded tops on which water was put a few moments after casting; they were also treated, while being cast, with 2 oz. of aluminum per ton of steel. They were, therefore, of rising steel deoxidized in the

molds, and should show somewhat greater tendency to piping than the first group; this is borne out by the results. The ingots of the second group required a discard averaging 8.0 per cent on account of pipe, while only one of the first group required a discard in excess of this amount (Table VI).

With respect to the "B," "C," "D," "E" and "F" positions for this group, the segregation is relatively low (max. 9.20 per cent, Table X) and uniform from one ingot to another as well within any particular ingot downward from the "B" position. The top discard for carbon segregation greater than 12 per cent (in "O" and "M" positions) is 23.3 to 25.3 per cent (Table XII) and within this discard the segregation is less extreme than in ingots of the first group, the maximum being about 25 per cent, which is attained in only two positions out of twenty-nine (Table XIII).

Group M11 to M15, Heat 2x4510. Two ounces of aluminum per ton was added to the ingots M11 to M15 for the purpose of deoxidation. The ingot tops, which were flat after pouring into molds, were not chilled with caps or water. These ingots were, therefore, of quiet, piping steel and apparently more nearly approach the type of steel represented by the Hadfield ingots than do the other two groups of Maryland ingots. They remained somewhat longer in the molds, 30 min. as compared with 20 and 23 min., before stripping and slightly longer in the soaking pits than the other comparison ingots.

FIG. 6. RAIL M5-F

Sulphur print shows pipe in rail from bottom portion of ingot. A—Structure along edge of bad pipe, eutectoid streak with large amount of slag bordered by hypo-eutectoid streak. B—Average moderately fine grained structure, pearlite with a trace of ferrite network and slag.

The considerable piping at the top of the ingots of this group is very strikingly characteristic of the above open-hearth and casting practice. The carbon segregation in the upper half and at the bottom of this type of ingot is slight, but there is developed negative segregation, ranging about 11 per cent at the "D" and "E" positions (Table X). In contrast to the other two types of Maryland ingot, except for M12, which shows other anomalies, the extent of the top discard is determined by piping (average discard 26.8 per cent) rather than by segregation (average discard 16.4 per cent; Table XI). The metallographic examination shows a small pipe in rail M15 at the bottom of the ingot in the "F" position, and incipient piping in M13 and M14 at the "B" position.

A striking characteristic of this group (M11 to M15) is the freedom from segregation in the "A" position; excluding M12A for which the segregation at "A" is 32.52 per cent, the average for the others is about 2 per cent segregation at the "A" position (Table X). M12 also possesses the following irregular segregation characteristics; at "A" there is segregation to such an extent that the microstructure is that of a hyper-eutectoid steel; at "B," a narrow hypo-eutectoid streak; at "C" there is the same structure as at "A"; and again at "D" a heavy hypo-eutectoid streak.

Segregation of Elements Other Than Carbon. In general it might be expected that the elements sulphur and phosphorus would follow carbon in segregation characteristics, and that manganese, silicon, chromium and nickel would show little or no segregation. These expectations are borne out in both the sink-head and comparison ingots.

Detailed studies showed longitudinal segregation of phosphorus to be absent for the "O" (tread) position and slight for the "M" (web) position. There is practically no longitudinal or transverse sulphur segregation in the sink-head ingots, while for the comparison ingots, the results on sulphur segregation are erratic (Table VIII), but on the whole follow the carbon segregation.

For the elements manganese, nickel, chromium and silicon there is no well-defined segregation within the ingot.

Part III will be published in a subsequent issue.

Analysis of Samples of Ancient Armor

The analysis and microscopical examination of about one dozen samples of ancient armor from the Metropolitan Museum of Arts, New York, have been practically completed by the Bureau of Standards. The analysis indicates that all the samples were made from very pure wrought iron converted into steel by the old cementation process, as would be expected.

The carbon determination was made on the entire cross-section, as the material of all the pieces was too thin and corroded to obtain samples from different layers.

The microstructure indicates that the process used in the production of the original iron was very similar to our wrought-iron process. The metal was then carbonized, probably by a supplementary process, hammered into sheets, differing in hardness—i.e., in the amount of carburization—and these sheets were welded together.

The whole was then hammered into shape and quenched, thus producing the final hardening effect.

New Hydro-Electric Project in Scotland

A project is on foot—and is, in fact, already taking concrete form—for the utilization of the water power now running to waste in the watershed of the Tay, with a view to generating an increased supply of electric energy for the counties of Forfar, Perth and Fife in Scotland, reports Consul H. A. Johnson of Dundee. Two schemes having the same object in view have already been before the public. In the first instance the government, through its water-power resources committee, investigated the possibilities of the Highland lochs and received reports upon nine distinct undertakings, the most productive of which, from the standpoint of power, was that in central Scotland for the utilization of the energy of Lochs Ericht, Laidon, Rannoch and Tummel. These, it was stated, would be capable of developing a continuous supply of 42,000 electrical horsepower at a cost on a pre-war basis plus 50 per cent of £1,580,000 (\$7,689,000).

The second was a project of the Dundee Corporation, which called for an expenditure of £4,000,000 to £5,000,000 (roughly \$20,000,000 to \$25,000,000), and under which it was proposed to utilize Lochs Ericht, Rannoch and Tummel. It was generally believed, however, that the task was too formidable for a city of the size of Dundee to undertake.

FEATURES OF THE NEW PLAN

The scheme now proposed is said to differ materially from those heretofore discussed. It appears that the matter now is in the hands of a group of business men and financiers, who have been investigating the possibilities of Lochs Ericht and Garry. It is claimed that from these two lochs alone 100,000 hp. can be developed with little difficulty, and this would be sufficient to furnish power and light to the three counties before mentioned. Italian engineers have been making extensive surveys through the Atholl Forest along Lochs Garry, Rannoch and Ericht. One of the noteworthy features of this new scheme is that there will be little damage to either sporting or agricultural interests, while under the Dundee Corporation scheme local opposition arose because of the destruction that plan involved. At this stage figures as to probable cost are not available.

ULTIMATE RESULTS EXPECTED

As to the ultimate results it is believed that there will be light, heat and power available for the three counties (which embrace the cities of Dundee, Perth, Forfar, Arbroath and Montrose) not only for the requirements of today but allowing for future expansion. It is understood that the company will not sell the power to the consumer but will bring it down to the various local authorities, who will buy it and distribute it themselves.

Manufacture of Fertilizers in South Africa

An explosives works near Cape Town is now erecting a large plant for the manufacture of fertilizers, which are very essential where agricultural industries are carried on in South Africa. Superphosphates, basic phosphates and nitrogenous fertilizers will be made. Small quantities will be available for the coming season. When the plant is running at full capacity—which will not be until next year—it will be capable of meeting the entire demand of South Africa.

Report of the Activities of the German Board of Trade During the War*

A Summary of the Official Board of Trade Report on the Conditions in Chemical and Allied War Industries, With Tabulated Data on the Wage Conditions and Accidents for the Period 1913-1918

THE extraordinary circumstances created by the war in the trades and industries have necessarily influenced the activities of the German Board of Trade. The reports of the Prussian Administration and Trade Authorities for the years 1914-1918 (official edition published by the Secretary of Commerce and Trade, Berlin, 1919) consist of a portly volume of 1,700 pages, giving an almost exhaustive account of the field of activity of the various officials of the Board of Trade and at the same time containing important documents on the German war industry.

The numerous articles in the German and foreign literature about the industrial production during the war have somewhat exhausted the subject; the official reports, however, treat matters from an entirely different standpoint. Much has been written about the important extension of the industries essential to war and of how astonishingly quickly the non-essential works had adapted themselves to the necessities of the day; but the influence of these changes and transformations on the general conditions of the working people is generally treated as a matter of secondary consideration. The official reports dwell at length on this influence. Page by page we are shown what efforts of all the interested parties were necessary, especially in view of the reduced personnel and the insufficiently trained substitutes to keep pace with the steadily increasing demands of the army and the war economy.

The fact that under such exceptional circumstances, aggravated by the steadily and increasingly depressing effects of the blockade, the accident-preventing measures and those for the hygienic protection of the workers did not suffer any noticeable impairment must be considered as a great feat for the German industry.

SPECIAL ACTIVITIES OF THE TRADE-CONTROL OFFICIALS DURING THE WAR

The normal activity of the Trade-Control officials during the period referred to was greatly burdened by the drafting of many of them into army service, and above all by the enlarged scope of their task, such as the examinations of the applications for leave of absence from the army and reinstatement in industrial work, the probing of applications for the release of confiscated materials and other such occupations benefiting the war departments to the detriment of the war industries. In addition these officials were called upon to give opinions and suggestions for the classification of the workers in very essential, essential and less essential occupations, to the co-operation in the care of war invalids, to help in the distribution of food, clothing and shoes, to handle the prisoners of war and even to handle the distribution of medals and certificates of

distinction—activities which, as can be easily surmised, are largely foreign to the Trade-Control Service when functioning under normal conditions.

INTERFERENCE OF THE MILITARY AUTHORITIES IN THE WORK OF TRADE INSPECTORS

The suddenness of the technical adaptation of many works for the production of ammunition brought the trade inspectors up against an accomplished fact before even they could take measures for the better security of the workers and of the population.

Complaints came in from the Government Trades Department of Potsdam that the military authorities had deliberately omitted to consult the trade inspectors about the advisability of changing certain works and that they encouraged many firms in their resistance against the trade officials. Similarly, reports came from the Department of Erfurt that most of the employers, encouraged by a circular from the Quartermaster General, considered that all the usual works safety measures were abolished. One may understand this procedure of the military authorities when the pressing demands from the "front" are recalled.

ACCIDENTS IN THE EXPLOSIVES INDUSTRY

In the course of the war, improvements were gradually introduced in practically all the industrial branches, particularly in the explosives industry. Factory experiences were exchanged. This was largely brought about by the important services rendered by a central war control office and a committee for the superintendence of munition and explosives factories.

The reports published by the unions in the chemical industries of all the accidents which occurred in the empire were of great help in improving working conditions. If, for instance, in seventy works in the Department of Potsdam, where explosives were manufactured, manipulated and stored, seventy death cases occurred through fires and explosions, such a death rate could not be considered as high, particularly in view of the circumstance that among the thousands of drafted workers many were physically and professionally poorly qualified for this line of work.

The Köln-Rottweiler powder factories in Premnitz for the manufacture of nitro compounds, erected in the course of the war, are given as an example for the average accident occurrences in this industry. Thus, with an average working force of 3,000 employees, the following accidents occurred during the years 1917 and 1918:

	Kind of Accident		
	Slight	Serious	Fatal
Burns by spilling of acid.....	33	17	..
Burns through fires in the centrifuges.....	18	8	..
Burns through ignition of gun-cotton and powder...	6	4	12
Burns through ignition of cannon charges.....	2
	57	29	14

*Abstracted and translated from *Chemiker-Zeitung*, July 11 and 17, 1920.

a Average minimum wage.

b Average maximum wage.

The reports of the Trade-Control Service bring out the details of these and similar accidents in many other works.

DEVELOPMENT OF THE WAR-TIME WAGE CONDITIONS

Special tabulated references are devoted to the development of the war-time wage conditions.

The increases in wages during the years of war appear relatively small when compared with the present scale of wages, which shows such an abrupt rise since the outbreak of the November, 1918, revolution. However, there was generally an increase of 100 to 150 per cent above the peace-time wages.

TABLE II. AVERAGE WAGES PER HOUR IN PFENNIGS IN BITTERFELD DISTRICT (TRADES GROUP VII)*

Trade	1914	1915	July 1916	1917	1918	Dec. 1918	Remarks
Locksmith	47	48	57	68	85	155	Add to this a bonus for children in some factories. During 1915 and 1916 the weekly bonus was 0.35 to 1.20 marks. During 1917 and 1918 the hourly
Building	45	45	55	64	77	130	
Engineer helpers	42	42	49	56	69	127	
Factory workers	42	42	47	54	67	124	
Laboratory workers	38	38	45	56	69	118	
All round workers	34	34	41	48	67	113	
Youths			42	42	52	65	
Female workers				37	45	80	

* Note the great increase in wages from July, 1918, to shortly after the signing of the armistice.

The developments in the wage conditions of today have their inception in the years of war—a fact which cannot be emphasized enough.

Tables I, II and III show examples of the average yearly, hourly and daily wages for workmen before and during the war.

SOCIAL WAR WORK IN THE INDUSTRIAL DISTRICTS

Great efforts were made by the War Industries Department to supply the workers with food and clothing in order to better their living conditions. For example, 10,000 persons were fed daily in two shifts by the Rheinische Metallwaren und Maschienenfabrik. The Farbenfabriken vorm. Friedr. Bayer & Co. in Leverkusen spent during the war for such purposes the round sum of 4,500,000 marks for distributing daily 8,000 dinners and about 9,000 war soups. A big cloth factory in the district of Dusseldorf supplied its employees

with large quantities of potatoes, cereals, milk, meats, etc., by leasing a 90-acre farm and also by cultivating the land around the factory. The Bergische Stahlindustrie in Remscheid established shoe-repair works and clothing depots for their workingmen and their families.

Many other similar examples are described.

The reports also contain a series of interesting details about the development of the social aspects in industrial works during the war.

WOMEN AS INDUSTRIAL WORKERS

As a result of the increasing demands for men, a great proportion of the workmen was drafted for military service and practically all factories were forced to take in women as substitutes. This generally had good results. As a general rule the women were not required to do too hard physical work. Naturally they were primarily considered for work at which unskilled labor had been previously employed. In the course of the war, however, many of them acquired knowledge of trades and became skilled workers. Occasionally women (in automobile factories) succeeded in getting the necessary training for machining shafts and spindles from working drawings.

Many employers, to reduce the physical effort of their women employees, introduced mechanical devices for lifting and other similar devices which proved to give greatly satisfactory results, especially in the ammunition industry.

SPECIAL LINES OF WORK PERFORMED BY WOMEN INDUSTRIAL WORKERS

Among the many special lines of work performed by women may be mentioned the following: Adjusting small motors, blacksmithing and mechanical work, making dies for punching machines, making, assembling and adjusting turbines; in the wood industry, veneering; in the chemical industry, filling grenades, gas mines and bombs, manufacturing powder, rockets; in the sugar factories, beet weighing and at the apparatus for diffusion, saturation, evaporation and vacuum. In the iron industry women were sometimes employed for handling the steam hammers. In the powder fac-

Women	3.00	4.00	5.00	6.50

tories they worked in the drying and mixing rooms, at powdering, screening, cutting and grinding machines; some women were employed to handle even the presses and in some instances they were called upon to handle the very dangerous kneading work.

The Control officials often made special mention of the courage women showed in performing very dangerous work.

The law of Aug. 4, 1914, gave the legal permission necessary for women to be allowed to do overtime and night work. During the war all the factories worked on the two and three shifts plan, with the result that night work steadily increased.

Complaints came from time to time about the moral deportment of the women workers; the increase in earnings resulted in the very detrimental policy of spending excessively for luxuries and amusements. In spite of this, the help of the women workers will be remembered with a feeling of deep gratitude. The male substitutes brought into the factories by the law regulating the auxiliary service did not prove as efficient by far as the women substitutes.

WAR-TIME ABROGATION OF THE CHILD LABOR LAW

The occupation of youthful persons also was extended largely. Very often the strict execution of the legal child labor protection measures had to be overlooked. The conduct of the youths in the factories was the subject of many complaints. The apprentice institution was badly neglected. Numerous young people did not enter in a factory as apprentices, but entered directly in the war industries as helpers. Due to the prevailing need for workers, apprentices were kept doing regularly one and the same kind of helper's work and consequently they could not learn anything else of the trade.

The lack of raw materials in many branches caused the discarding of many trades altogether. In many cases the employers had to be reminded not to lose sight of the interests of the trade when normal times should arrive and afford to their apprentices a regular trade instruction.

STATISTICS OF INDUSTRIAL ACCIDENTS FOR THE PERIOD 1912-1918

As stated before, the hygienic condition of the various factories was very satisfactory when the exceptional conditions created by the war are considered. It is surprising to find that in those groups of industries which employed the largest number of workers and where the absolute number of accidents had naturally increased there was a lower relative percentage in the frequency of accidents. (See Table IV.)

This is explained by the fact that even in the branches of ammunition production, to which the trade-groups listed as V, VI and VII owe their powerful development, the number of persons employed in non-dangerous and easier kinds of work was the larger. Another cause of the low percentage of accidents in this line of work was the introduction of the method of working by shifts, which did not permit the workers to get overtired.

The relative number of accidents in factories with

* The percentage could not be figured out, as there are no reliable data on the number of employees during 1914

reduced personnel was much greater, due to the fact that the best and most reliable employees were lost either by drafting to the war service or by migration into ammunition industries, in consequence of which difficult work was often performed by unskilled substitutes.

ACCIDENTS DUE TO THE TOXICITY OF THE MATERIALS USED

The fatal cases from poisoning by nitrous gases were relatively numerous, due to the increased number of plants for the production of explosives. The poisoning effect of the finished explosive materials in plants taking up the filling was generally not so apparent. Only dinitrophenol makes an exception, causing occasionally serious poisonings with quick fatal issue.

Nitroglycol should be treated more cautiously than nitroglycerine on account of its higher volatility. In manipulating it the workmen experienced at first a feeling of dizziness and blood congestion; later they became used to it.

Trinitroanisol produced dermatitis and eczema by the action of its dust particles on the unprotected skin. In a plant where the hygienically harmless trinitrotoluol was employed several persons died one after the other, all from acute atrophy of the liver. This was probably due to the use of a trinitrotoluol which was admixed with poisonous impurities.

Unpleasant skin eruptions occurred, particularly in summer time, at the plants using silver fulminate, but no serious poisonings ensued from this cause.

The toxicity of benzene is as a rule underestimated; it was employed on a large scale as a substitute for benzine and was not treated cautiously enough. Quite a number of death cases occurred in benzene depots and in laundries from this cause. Painters and varnishers suffered much through the vapors of benzene, which was an ingredient of their paints, particularly when confined to the narrow space of a ship. Similar hardships resulted at the manufacturing and manipulation of cellon varnish, which was extensively used for various purposes; the solvents for it (ketones, methanol, chloroform, ethyl formate) caused dizziness and fainting spells, also irritation of the eyes.

ACCIDENTS DUE TO THE USE OF SUBSTITUTE MATERIALS

The use of Ersatzmaterialien—substitute materials—led to unexpected accidents. The serious explosion which destroyed the trinitrotoluol factory of the chemical works Griesheim-Elektron, in November, 1917, was due to the overheating and burning of a nitrator. This accident, it is explained, was caused by the fact that the asbestos rope used for tightening the manhole cover contained a large admixture of cotton which had undergone a nitrification and ignited spontaneously.

SOME IMPORTANT TRADES GROUPS IN THE POTSDAM DISTRICT

Average Accidents Reported in 1916 and 1917 per 1,000 Workers					Accidents reported in 1918 per 1,000 Workers					Number of Employees

d 1915.

In a compressed air plant a rather serious explosion occurred when instead of the war lubricating oil, which gave up considerable pitch, a cylinder oil of a 200 deg. C. flash point admixed with petroleum was used for the compressor; the petroleum probably formed an air mixture, igniting at 140 deg. C., the temperature of the exit air in the compressor.

The bad material for belting caused many accidents.

Skin eruptions produced by oils assumed proportions unknown heretofore. They occurred on persons who had to work with substitute lubricating and drilling oils. The use of unfit substitutes and the lack of cleansing and washing articles were the main causes for it. Women particularly had to suffer from these annoying skin diseases, which appeared usually on the hands and forearms, but spread also to other parts of the body and very often caused fever and general impairment of health. In many works petrolatum was distributed as a protective ointment; linoxyl soap was recommended as a cleanser.

OTHER ACCIDENT CAUSES

A woman working at the turning bench of a cartridge factory had her celluloid comb take fire by a glowing steel chip and suffered in consequence serious burns.

At a plant manufacturing aceto-acetic ester two workmen died from burns. The cause is explained by the fact that during the chemical reaction combustible vapors were given off and were ignited by the sparks of a passing locomotive.

In filling bottles with fluid hydrocyanic acid from steel containers an explosion occurred, killing two men; later on several more containers exploded—this time in the yard.

The report adds: "After thorough investigation, fluid hydrocyanic acid is to be classed as an explosive material and its use for the destruction of moths in mills appears doubtful." This remark goes too far and is misleading. Fluid hydrocyanic acid is under certain conditions sufficiently stable, but requires careful handling.

In some instances hydrogen was pumped, by mistake, into oxygen containers and this resulted in many accidents. The cause of the mistake was that the oxygen and hydrogen containers could not be clearly distinguished. This was remedied by making the containers and the caps of different diameters for the two kinds of gases.

Very little white lead was manufactured during the war, and on account of this few cases of lead poisoning were reported. There was an increase in lead poisoning cases in the printing trades due to the lack of washing materials. The Farbenwerke A.-G. in Dusseldorf took advantage of the standstill of their white-

lead plant to introduce improvements not requiring manual labor in their oxidation chambers.

LIQUID AIR AS A BLASTING MATERIAL.

Of special interest are the reports of the superintendents of the mining districts covering statements about the introduction of the air-blasting process and the accidents caused by it. As there was

a big shortage of safe blasting materials from the beginning of the war, the use of liquid air as a blasting material started as early as 1915. According to the opinion of the inspecting officials, few of the accidents which occurred were due to the use of the new blasting method. The poor quality of the accessories—ignition cord, blasting capsules, spark plug—was the direct cause of many accidents in blasting with liquid air.

Use of Compressed Gas in Foreign Countries

A number of consular officers have made special reports on the use of compressed gas. These reports may be examined at the Bureau of Foreign and Domestic Commerce or its district offices.

Consul General Roberston, at Buenos Aires, Argentina, reports that it is used for various purposes. The gas is manufactured locally and the output of the factories is used by the entire republic. The machinery for its manufacture was originally imported from France and Germany. The consul general says that there should be a fair market for equipment for utilizing gases for industrial, hospital and laboratory uses. The most feasible method of marketing machines for gas manufacture or for its application industrially is by giving the representation to one of the large American commission houses which has the advantage of technical experts and knows the machinery market thoroughly.

Compressed gases are used in Ottawa, Canada, according to Consul General John G. Foster, in connection with industrial establishments and hospitals. The hospitals and the dentists obtain their supply from the dental-supply houses, the largest being in Montreal and Toronto. It is stated that these firms, which have branches in the principal Canadian cities, import all the gas and oxygen used from the United States. Importation is made in large cylinders, the gas being repumped into smaller ones for distribution.

Vice-Consul John C. Moomaw, at Bombay, India, writes that compressed gases are generally used by the principal engineering, shipping, dock and railway concerns in his district for welding and cutting metal; also in many of the hospitals. The gases are of local make, being supplied by a branch of a large British house, which also furnishes machinery and equipment for gas application.

In Sweden compressed gases are being used extensively for welding, according to a report by Consul Walter Sholes, at Goteborg. Shipyards and larger shops produce the gas in their own plants instead of buying cylinders with compressed gas. Machinery for the production of compressed gas was formerly obtained in Germany and France, but Sweden now supplies its own markets.

The Present Status of the Electric Furnace in the American Metal Industries*

Present Technology and Future Possibilities of the Electric Furnace as Applied in the Manufacture of Synthetic Cast Iron, Steel, Steel Castings, Ferro-Alloys, and in Heat Treating, Brass Melting and the Smelting of Non-Ferrous Ores

By ROBERT M. KEENEY

THE development of the electric furnace to a position of great industrial importance during the last decade was one of the most noteworthy steps in the progress of metallurgy. In 1910 there were electrometallurgical power loads in about twenty-five cities in the United States and Canada. Today such a load is found in over 200 cities. Ten years ago so little was known of the characteristics of an electric-furnace load that few companies cared to have an electric furnace on their lines. Today, with an electric steel furnace in practically every manufacturing city in the country, the load is considered desirable and is much sought. The wide extension to so many communities is, of course, due mainly to the war. Although the number of steel furnaces installed during the past few years is far greater than could have been foreseen ten years ago, and although many were installed mainly for war purposes, it does not appear that there has been an overdevelopment in this respect. The quality of electric steel has become so well established that the electric process is here to stay, and it will probably eventually supersede other processes for the production of castings, and super-refining will be practiced on a large scale for treatment of molten bessemer and molten open-hearth steel. The electric furnace load of the United States and Canada for the production of steel, ferro-alloys, brass, zinc and silver amounts to approximately 800,000 kva.

FIG IRON

Although the electric smelting of iron ore was developed simultaneously in the United States and Sweden, and although in 1908 D. A. Lyon erected here in California, at Heroult, the first electric furnace to produce pig iron commercially, the process is no longer in operation in this country. Pig iron is being produced in the United States by electric melting of scrap, not by smelting iron ore. On the other hand, development in Sweden and some other countries has been steady. The furnace used is similar to the shaft furnace installed by Lyon in 1908, which is especially adapted for production of low-carbon and low-silicon iron, but not foundry iron. It operates best with charcoal as a reducing agent, and has proved a failure when operated with coke. The pit type furnace, with no shaft except charging spouts, operates satisfactorily with coke, and also produces foundry iron. The last two furnaces operated at Heroult were of the low pit type, and could be operated with coke and charcoal mixed for production of high-grade foundry iron. In 1910 there were in operation two electric iron-smelting furnaces

of a total input of 3,500 kw. At the present time there are installed thirty-three electric iron-smelting furnaces of from 2,000 to 7,000 kva. capacity, with a total load of 100,000 kva. and a production capacity of 250,000 tons of pig iron per year. During the war production costs have favored electric smelting, so that electric pig iron is now being produced in Sweden for \$5 per ton less than blast-furnace charcoal iron. This is in spite of an increase in power cost of 50 per cent which has raised the average cost of power from \$8 to \$12 per horsepower-year.

Electric-furnace production of pig iron will probably never develop to any great extent in the United States along the line of development in Sweden, because of the high cost of power, but I believe that the time is coming, particularly in the Western States, when pig iron, more specifically cast iron, will be made by melting of scrap iron, scrap steel, iron ore, coke and lime in the electric furnace to produce iron for direct castings or for pigs. During the war a considerable quantity of low-phosphorus pig iron was made in the United States and Canada by electric melting of steel scrap. The Canadian production in 1918 amounted to 32,200 tons. Toward the end of the year it was at the rate of 4,000 tons per month. Six plants were in operation in Canada and two in the United States. There seems to be a future for the process, especially in foundries where the cost of foundry pig iron is high, due to freight. I know of one mountain city where the foundries pay \$55 per ton for pig iron laid down at their plants. Iron in the ladle could there be made by the electric process for \$35 per ton.

The metallurgy of synthetic electric-furnace cast iron, as it is called, was worked out on a large scale in France during the war. Three plants were erected with a total power input of 40,000 kva. During 1916, 1917 and 1918 220,000 tons were made with metal cast direct from these electric furnaces, of which there were sixteen of from 1,000 to 2,200 kva. capacity. Power consumption is from 675 to 800 kw.-hr. per ton of cast iron. Any grade of iron desired can be produced. The process is conducted as a continuous operation, with the furnace kept full of charge. With a large unit the load is very steady, but it is probable that in the operation of small units there might be a tendency to momentary overloads. These would be no worse than in a steel-melting furnace. The power factor of the furnaces is about 80 per cent on sixty-cycle current. A phase voltage of 50 to 70 volts is used.

REFINING GRAY IRON

Another use of the electric furnace is in refining gray iron from the cupola. Cupola iron, after treatment in the basic electric furnace, shows a marked

*Read before the National Electric Light Association meeting at Pasadena, Cal., May 20, 1920.

decrease in sulphur and an increase in transverse strength. At present, because of costs, the process appears adaptable only for the very highest grade of castings. The electric furnace is also being used for the production of malleable iron castings. It has furthermore been considered as a mixer for keeping molten blast-furnace pig iron hot for casting it into pipes in ingots.

STEEL

The most marked increase in the use of central station power electric furnaces during the past ten years has been in the electric-furnace manufacture of steel. In 1904 there were four small furnaces in operation in Europe. In 1907 there were sixty-seven furnaces in operation throughout the world. Of this total, seven were installed in the United States and Canada, with a total power input of 5,600 kva. and a charge capacity of forty tons per heat. On Jan. 1, 1920, there were installed or under construction in the United States and Canada 363 furnaces with a total charge capacity per heat of about 1,600 tons and a total power input of about 600,000 kva. Of the 363 furnaces, 323 were installed in the United States and 40 in Canada. The number of electric steel furnaces in the world is estimated at 875.

The production of electric-furnace steel in the United States in 1918 was 511,364 gross tons. Almost 50 per cent of the production was alloy steel. Of the 323 furnaces in this country 54.5 per cent are being used for castings. The percentage of the tonnage of 1918 produced as castings was 21.1 per cent of the total.

There has been a great development in the use of the electric-steel furnace for the production of ingot alloy steels for automobile construction and high-speed steel. The electric furnace operating with a basic lining produces tons of high-grade alloy steels per heat as compared with the crucible furnace producing pounds. Lower grade raw materials can be used because of the possibility of refining to remove phosphorus and sulphur. The furnace has proved particularly successful in the production of alloy ingots such as chrome-vanadium steel, turning out a product better in quality than similar open-hearth steel with a much lower loss of alloys by oxidation.

For the production of high-speed steel in large heats the electric furnace proved well adapted during the war, it being common practice to pour 5-ton heats of steel valued at \$3 to \$5 per lb. However, the substitution of the electric furnace for the crucible furnace will be gradual, because it is not yet demonstrated that average electric high-speed steel is quite equal in quality to the highest grades of crucible high-speed steel. To meet the grade of highest quality crucible steels, the electric-furnace product must be made from the purest raw material available, and even then, considering electric steel versus crucible steel from the conditions existing in each case, it does not seem possible that melting conditions can be as closely controlled in the electric furnace as in the crucible. This statement applies only where the operation is the simple melting of pure material.

A future probable large development in electric steel is the use of the furnace for finishing molten converter and open-hearth steel. The Illinois Steel Co. has installed ten 30-ton electric furnaces to treat steel which has been first blown in the bessemer converter, then held in the open hearth, and eventually transferred to the

electric furnace. This process was used to a small extent in the early days of electric furnace steel production in this country, and a few years will probably see its general adoption.

ELECTRIC STEEL CASTINGS

In 1910 of the total production of electric steel in this country 2.53 per cent was as castings. In 1918 there was manufactured 108,296 tons of electric steel castings, representing 21.1 per cent of the total production of electric steel. Except for the manufacturers of high-speed steel, most companies producing alloy steels, such as chrome-vanadium steel, generate their own power, and do not buy from a central station, because the electric-furnace plant is usually a part of a large steel plant. This is especially true in plants using the duplex process for refining molten steel. On the other hand, practically all foundries buy their power. Electric-steel castings can now be made more cheaply than converter castings, and at as low a cost as open-hearth castings. The grade of the casting is better than the product of either of the other methods.

A great advantage of the electric furnace over the open hearth is the rapidity with which heats are made, so that it does not require handling of large quantities of metal as in the case of the open hearth. Within a few years the electric furnace will probably replace all other processes for making steel castings, and most castings will be produced without refining, by melting scrap on an acid bottom.

Aside from the fact that the skill shown in furnace operation may cause a low load factor, most foundries operate on a 10-hr. day instead of a 24-hr. day, so that with 10-hr. operation a load factor of 18 to 30 per cent is obtained. On a 24-hr. day the load factor will vary from 40 to 55 per cent when making castings. This low load factor, as compared with other electrometallurgical industries, is caused by time lost in charging and pouring when the power is off. Due to greater length of time between pourings, a furnace producing ingots on a basic bottom with refining should have a higher load factor than those mentioned, but this is offset by the present common practice of running with about half or one-third load during the refining period at the end of a heat. A furnace refining molten steel instead of melting cold scrap should attain a load factor of 75 per cent on 24-hr. operation.

The power consumption varies from 550 kw.-hr. per ton when melting scrap on an acid bottom for castings to 1,000 kw.-hr. per ton when making high-speed steel ingots requiring refining. The voltage on the only type of single-phase furnace now used is about 140 volts on the arc, 220 volts open circuit. On two- and three-phase furnaces the voltage is from 90 to 110 volts. The power factor of the single-phase furnace mentioned varies from 50 to 70 per cent due to heavy reactance in the circuit. The two- and three-phase furnaces have power factors of from 85 to 95 per cent. The electrode consumption is 15 to 25 lb. per ton of steel.

NEW TYPES OF FURNACES BASED ON THE ORIGINAL HEROULT FURNACE

During recent years the tendency in electric-steel furnace construction has been to increase the power input per ton; to use three-phase current and automatic regulators; not to have large reactances in the primary circuit; and not to build furnaces with a bottom electrical

connection, at least a connection carrying all of the load. In fact, now that the basic Heroult patents have expired, most new types of furnaces appear to be the original Heroult furnace embellished and camouflaged, which is probably a good thing. The power input per ton of charge has been increased from 170 kw. in the early furnaces to 500 kw. in the most recent steel-casting furnaces. One furnace has been built with electrical connection permitting cutting the secondary voltage in half during refining. The use of three-phase current has become almost standard either as three-phase current in the furnace or three-phase converted to two-phase. Few single-phase furnaces are being built. The single-phase furnace with the bottom contact, however, blazed the way for rapid melting of scrap for steel castings on an acid bottom and the use of heavy power input per ton of charge.

The use of heavy reactance in the circuit is being discarded with few exceptions, and furnaces are generally operated with a moderate reactance and automatic regulators. Common reactances are 7 per cent to 15 per cent in the transformer. The bottom contact, as used for carrying all of the current, has apparently gone out of use with the gradual abandonment of single-phase furnaces, although it is still used for putting a small part of the current through the bottoms of some two-phase and three-phase furnaces.

The furnace with a moderately high power factor, 80 to 85 per cent, has proved to be a better load for the central station than the furnace with a very high power factor, 95 per cent, because it is not so sensitive to short circuits in the furnace, and at the same time there is enough reactance present to render electrode regulation easy with regulators. The use of furnaces with heavy reactances and hand regulation of electrodes should be discouraged, as the heavy reactance is not necessary if regulators are installed.

ELECTRICAL HEAT TREATING

Electric furnaces of the carbon resistance type have been installed in considerable number for the heat treatment of forgings and castings. The furnaces are ingeniously designed with a very complete automatic control of temperature, and control movement through the furnace of the piece being treated. The heating is by a resistor of granular carbon confined in carborundum fire sand troughs, which results in a uniform load without surges and a power factor of 98 per cent or better. The load on the furnace is controlled by variation of secondary voltage with taps on the secondary of a special type of transformer. The electric heat treatment of steel is certain to become common practice even at a higher cost because of the ease of control and uniformity of the results obtained. Single-phase furnaces of 900 kw. power input have been installed alone or with two or three connected in balance on a three-phase circuit and operated successfully. A further advance is the adaptation of this type of electric furnace to the soaking pit for large steel ingots and billet reheating furnaces.

Another type of electric heat-treating furnace was developed during the war, in which the heating unit consists of a nickel-chromium alloy ribbon mounted on a cast-iron supporting plate and insulated therefrom by suitable refractory material. The furnaces are of the cylindrical, vertical type and take three-phase 440-volt current. Units of 400-kw. capacity have been built. The current is automatically thrown off and on as the

temperature rises above or falls below the desired point. These furnaces were designed for the heat treating of gun barrels, but can readily be adapted for the industrial uses of the future.

FERRO-ALLOYS

The war demand brought the electric-furnace ferro-alloy capacity to a point which, with the arrival of a more normal peace demand for ferro-alloys, puts the industry in much the same condition as existed in the European calcium carbide industry in 1899, when overproduction and patent litigation compelled most plants to look for new products, which strangely proved to be ferro-alloys. The increase of installed furnace transformer capacity for ferro-alloy production was enormous from 1915 to 1918. In 1910 there were only two plants in the United States which produced ferro-alloys in the electric furnace. They had a total transformer capacity of possibly 20,000 kva. On Jan. 1, 1920, there were forty plants with a combined transformer capacity of 200,000 kva. At the date of discussion, probably 75 per cent of these plants are not operating.

With the enormous increase in plant capacity the United States easily led the world in production of ferro-alloys when the armistice was signed. The plant capacity of ferrosilicon has increased from 10,000 or 15,000 tons per year to 100,000 tons per year. Instead of importing ferrotungsten and ferrochrome, large quantities were exported. Ferrovanadium, which had always been exported, was shipped abroad in larger quantities than ever. But the two most important developments have been the electric smelting of manganese ores and the increased use of molybdenum in steel.

In 1914 there were no electric smelting plants built for production of ferromanganese. On Armistice Day there were ten plants of total transformer capacity of 55,000 kva. and production capacity of about 80,000 tons per year. At the close of 1918 about 15 per cent of the ferromanganese production of the United States was being made in electric furnaces. With two exceptions these plants are now out of operation, the two largest having resumed work when the price of ferromanganese advanced several months ago.

Through the interest of one of the largest smelting companies in the world in a Colorado molybdenite deposit, which is probably the most extensive known deposit of molybdenite, containing at least 100,000,000 tons of 1 per cent ore, large-scale investigation of the use of molybdenum in steel has resulted. This work shows that the addition of small quantities of molybdenum to chrome, nickel, chrome:nickel or chrome:vanadium steel results in a steel of greater strength and toughness, which is easily forged, easily heat treated and easily machined. Probably 300 tons of ferromolybdenum were produced in 1918 as compared with less than twenty-five tons in previous years. There was a very small production in 1919.

Practically all ferrosilicon furnaces are now installed in three phase units. If it is desirable to install units of less than 1,500 kva. capacity, a single-phase furnace with two vertical electrodes in series is usually built. There is at least one plant in this country equipped with single-phase furnaces of this type. All of the large ferromanganese furnaces erected in this country are of the three-phase type. The ferromanganese furnace gives about the smoothest and most easily controlled load of any of the ferro-alloy furnaces.

Ferrochrome is made in both single-phase furnaces

and three-phase furnaces. Before the war an engineer from the largest point of ferro-alloy production, Niagara Falls, claimed that ferrochrome could not be made in a furnace of over 1,000-kw. capacity. This was proved to be a fallacy by the recent installation of a 1,500-kw. furnace in Denver which operates more satisfactorily than a smaller furnace at the same plant.

Ferrotungsten is almost universally made in the single-phase furnace of the Siemens type with the bottom forming one electrode. The metal is allowed to build up in the furnace and the furnace torn down to remove it. This results in considerably more irregular load curve than with the larger tapping furnaces. One plant, now dismantled, successfully made ferrotungsten in a three-phase furnace.

The characteristics of ferromolybdenum operation are much the same as for ferrotungsten, except that when the 55 per cent molybdenum alloy is being made, it can be produced in a tapping furnace instead of a knock-down furnace.

Electric furnace ferrovanadium is usually produced in a single-phase furnace, either of the Siemens type or series type.

Ferro-uranium is made in small furnaces of the Siemens type. Due to absence of slag in the operation, the load is very irregular, and considerable reactance is usually used in the circuit, especially if automatic regulators are not used. The load characteristics of a ferrotitanium furnace are somewhat similar to those of ferro-uranium.

In commercial production of these ferro-alloys, ferro-silicon, ferromanganese and ferrochromium can be made in three-phase furnaces as readily as in single-phase furnaces, and there is no reason for permitting installation of single-phase furnaces for their production. Ferrotungsten, ferromolybdenum, ferrovanadium, ferro-uranium and ferrotitanium must be made in single-phase furnaces. At least the operation is much more apt to succeed in a business way. It may be noted that the line of division in these alloys is between metals of a low melting point and metals of a high melting point. Silicon, manganese and chromium have comparatively low melting points when electric-furnace temperatures are considered, while the melting point of tungsten, molybdenum, vanadium, uranium and titanium is high.

Some power companies seem to have an idea that electric ferro-alloy furnaces can run on any old voltage. If possible an endeavor should be made to deliver power at a constant voltage throughout the twenty-four hours of a day. Recently I put in operation a ferro-alloy plant with the understanding that the primary circuit was 4,500 volts. Furnace transformers were installed with a ratio of 4,500/75. During the twenty-four hours the secondary furnace voltage varied from 72 to 85 volts, depending on whether the industrial load of the town was on or off. This results in two things—it ran up the demand charge, because the furnace would run at the same amperage with higher voltage unless watched continuously, and means the production of a poorer grade of metal when running a knockdown furnace, as the button will not be so compact with high voltage. The difficulty was not caused by anything in the furnace transformer, which had a reactance of 7 per cent, as the same ratio of variation was shown on the 110-volt lighting circuit. In another case a large furnace was installed on a power line which the power company

claimed was more than heavy enough. It resulted in a line drop of 25 per cent, which made the furnace voltage so low that enough power could not be got into the furnace to keep it hot. Ferro-alloy furnaces are run on certain voltages because practice has proved these voltages to be the best. Of course, in 3,000 to 4,000-kw. furnaces it is necessary sometimes to raise the voltage above the desired limit for good metallurgical practice in order to get power into the furnace.

The electric-smelting load, at the present time exemplified by ferro-alloy furnaces, is probably one of the best loads a power company can get, and in the future may prove a much larger load with application of electricity to smelting of non-ferrous ores, which is not such a dream as it may seem at present.

BRASS

There has been a remarkable growth of the use of the electric furnace for melting brass and non-ferrous metals. From one silver-melting furnace of the carbon resistor type in 1914 the number has grown to 261 on March 1, 1920. Of these furnaces 61 are carbon resistor furnaces, 118 are induction furnaces and 82 are arc furnaces of various types. Furnaces are being used to melt brass castings, wrought brass, bronze, copper and nickel. The total estimated installed transformer capacity is 23,000 kva., of which one-third is on carbon resistor furnaces, one-half on arc furnaces, and the remainder on induction furnaces. The carbon resistor furnaces operate at 98 per cent power factor, giving a very steady load. The most common size has 105 kva. transformer capacity. The induction furnaces are built in the smallest units of any of these furnaces, taking 30 to 60 kw. load with a power factor of 70 to 85 per cent. The indirect rotating arc furnace operates at 80 to 90 per cent power factor, and is built in sizes up to 300 kva. Depending on the kind of brass being melted, the power consumption varies from 250 to 400 kw.-hr. per ton. All of the brass furnaces are single phase except one type of three-phase furnace which has not been widely installed for this purpose.

ZINC

Although there has been considerable experimenting in the United States and Canada during the past ten years on electric smelting of zinc ores, nothing has been done in commercial production. Electric smelting of zinc ore and dross has been practiced commercially in Sweden since 1901. Two plants are in operation in that country, with a total transformer capacity of 15,000 kva. A large part of this capacity has been used for smelting dross. When smelting ore the main difficulty has been in production of blue powder instead of zinc. Single-phase furnaces of 350 to 750 kva. size are used. Although the blue powder difficulty appeared practically solved by experimenters in the United States several years ago, nothing commercial has resulted. Electric smelting of zinc ore in the United States will possibly at some time be accomplished in a commercial plant. It is much better adapted to operation in small units for isolated mines than the electrolytic process.

A large 1,000-kw. melting furnace of the carbon resistor type was put in operation in 1919 for melting the zinc cathode in an electrolytic zinc plant. In the first weeks of operation it is reported that the furnace melted zinc with a power consumption of 70 to 80 kw.-hr. per ton of metal, and a metal loss in dross of 0.024 per cent.

In addition to the cheapness of the power, the character of the power contract negotiated and the basis of figuring rates will have some effect on the efficiency of operation of the electric furnace. I believe that electric furnaces, particularly smelting furnaces, are operated at their highest efficiency under contracts which provide for a flat charge per kilowatt-month, based on the maximum demand, rather than a charge which includes a maximum demand charge and a kw.-hr. charge. Under such a contract the furnace operator is compelled to install small units for a continuous operation of twenty-four hours per day rather than a large unit to be operated only ten hours per day. In the end it means a better load for the power company, and will probably mean money saved for the furnace plant. Under such a contract the power company is protected to the extent of its overhead charges by the minimum guarantee payments if the plant should not be operated continuously. Under such a contract I have operated plants in which the process was intermittent at a load factor of 70 per cent, and in plants where a continuous process was being used have run at an average load factor of 85 per cent.

In the contract under which I have operated, the power factor must be over 75 per cent, and the maximum instantaneous demand cannot exceed 300 per cent of the normal rate. The power company also requires that the load on any one phase shall not exceed the load upon any other phase by more than 15 per cent. There has been no difficulty in meeting these requirements.

FUTURE DEVELOPMENT

In melting steel and non-ferrous metals and electrolytic refining of metals a power cost of 1c. per kw.-hr. is reasonable, but a smelting process or electrolytic reduction process, except when producing the high priced ferro-alloys, such as ferrovanadium, cannot stand this price. The smelting-furnace operator does not expect the two-mill power of Sweden, but in most cases he must have five-mill power. The present cost of power limits the following electrometallurgical processes to hydro-electric power: the smelting of iron ore, ferro-alloy production, aluminum, electrolytic zinc precipitation and the electric smelting of non-ferrous ores.

The price of coal and oil has reached such a point in many Western smelting centers, where hydro-electric power is available, that if electric furnaces were developed to a point where they could be substituted for combustion furnaces, substitution of electric furnaces would undoubtedly result. This development is certain to come before many years if fuel prices remain high, particularly oil.

Modern industry demands high-grade products. Even if electric-furnace steel costs slightly more than open-hearth steel, the requirement of the best steel possible for present-day industrial purposes is certain to result in a large increase of the production of electric-furnace steels and non-ferrous alloys. This will eventually increase the consumption of electrically produced ferro-alloys.

In summary, a considerable increase of the uses of electricity is to be eventually expected in the following processes: (1) iron castings from scrap or a duplex process of cupola melting with electric-furnace refining; (2) steel castings and alloy steels; (3) ferro-alloys; (4) aluminum; (5) brass melting; (6) electrolytic zinc; and (7) electric smelting of non-ferrous ores.

The National Bureau of Standards

THE National Bureau of Standards was created on March 3, 1901, by an act of Congress. It is charged with the development, construction, custody and maintenance of reference and working standards and their intercomparison, improvement and application in science, engineering, industry and commerce. Besides the standards of measurement, such as standards of length, volume, heat, light, electricity, etc., there are standard constants, an example of which is the mechanical equivalent of heat; the standards of quality, as exemplified by specifications; standards of performance,

U. S. BUREAU OF STANDARDS BUILDINGS

such as the ratings of engines, boilers, dynamos and other machines, and standards of practice, which include the various building and safety codes, etc.

DIVISIONS OF THE BUREAU

For purposes of organization, the bureau is divided into nine scientific divisions, as follows: Division of Weights and Measures; Electrical Division; Division of Heat and Thermometry; Optical Division; Chemistry Division; Division of Engineering Physics; Division of Structural, Engineering and Miscellaneous Materials; Division of Metallurgy, and the Ceramics Division.

ITS WAR-TIME ACTIVITIES

While the application of science to the industries was recognized by a few of the more advanced manufacturers in this country, its importance to our national life was not generally realized until the war had been in progress for some time. It was then found that science was a very practical proposition without which it was impossible to make any headway. The detection of airships and submarines, the location of hidden guns, the manufacture of substances the supply of which was cut off, were a few of the problems put up to the scientist by the military departments. The Bureau of Standards suddenly found itself the center of a vast number of activities which required a great increase in its personnel and equipment.

Supremacy in peace is no less dependent upon science and standardization, and this should not be lost sight of at this time when the tendency to revert to old times is so great—what we have gained we should hold.

Legal Notes

BY WELLINGTON GUSTIN

Seller Must Prove Product Possessed Quality Desired Where Such Is Known to Him

In the case of the James K. Thompson Co. against the International Compositions Co. judgment for the former was reversed and new trial granted by the New York Supreme Court, Appellate Division.

The plaintiff Thompson company sued on contract for the price of a quantity of copper oxide. The oxide was sold for the specific purpose of making a high-grade anti-fouling marine paint. The seller knew that there was required for the work a very fine grade of copper oxide, and the first two deliveries were fully up to the standard required by the buyer. However, the third delivery was claimed to have been much coarser. There were foreign substances in it and it would not pass through the fine sieve that the other oxide delivered would pass through. The buyer claimed this violated the requirements of the contract of sale. But before discovering the defect in this article it had used about one-third of this defective third shipment, and in making paints therefrom it made paint utterly useless and which was returned by its patrons, and the buyer claimed damages by reason of the loss of other materials that it put into the paints which were thus rendered unsalable by reason of the defective copper oxide, such damages amounting to double the seller's claim.

The rule of law is laid down that the seller, having knowledge of the fine quality of oxide required by the buyer for the making of marine paint, has the burden of showing that he furnished the required quality. And the defendant, urging a counterclaim, has the burden of proving same.

Indorsement on Check Insufficient to Discharge Whole Claim in Dispute

The Supreme Court of Errors of Connecticut has reversed the judgment obtained by the defendant Premier Manufacturing Co. in the suit brought against it by the Crucible Steel Co. of America, and ordered judgment for the latter.

Crucible Steel brought its action to recover for goods sold and delivered under five separate invoices. There was no dispute concerning the first three. The two others were in dispute because it was claimed the products had been shipped from Pittsburgh instead of New Haven, Conn., as ordered, and that the goods were not received. Defendant sent its check for the undisputed items. Subsequently this action was brought to recover for the two items remaining unpaid together with some incidental charges. The Premier company defended on grounds of accord and satisfaction and that it had never received the merchandise. The trial court found the Premier company had received the merchandise, that it had paid for the incidental and other charges against it, but gave it judgment on the issue of accord and satisfaction, as shown by payment of its check. On back of the check were the words "In full settlement of invoices to date," etc.

In tendering the check the Premier company intended

to pay its entire indebtedness to the Crucible company according to the former's understanding of it, and to settle thereby all matters in dispute with the Crucible company up to the date of the check. The latter accepted the check, gave credit on its books for the invoices listed on the back of the check, and continued to bill the Premier company for the other invoices and items charged against it.

Commenting on the defense that acceptance of the check was an accord and satisfaction of the disputed account, the Supreme Court said the defense of accord and satisfaction requires the defendant to allege and prove a new contract based upon a new consideration, and there must be a meeting of the minds of the parties, and the new consideration must be offered by the debtor and accepted by the creditor with intent to satisfy the whole claim, and the fact that such sum is offered in discharge of the whole claim must be made known to the creditor in some unmistakable manner.

Further, the court held that the memorandum on the back of the check was insufficient to express clearly the condition that, if accepted, it must be accepted in satisfaction of the entire amount claimed by the creditor on five separate invoices, thereby precluding the Crucible company from suing for the balance.

Fraudulent Representations Do Not Make Fertilizer Fraudulent Under Statute

The Supreme Court of Louisiana has reversed the judgment of the lower court in the action by the Planters' Fertilizer & Chemical Co. against Barton & Barton, ordering judgment be entered in favor of the chemical company for \$5,719.15 with 6 per cent per annum from June 22, 1913, and that costs of the suit also be paid by Barton & Barton.

The company sued for the price of fertilizer sold Barton & Barton as per contract. The defense was that the agent who negotiated the sale for the chemical company represented that the fertilizer would contain 8 per cent ammonia in the form of either cottonseed meal or tankage, whereas it contained ammonia in neither of these forms, and proved to be valueless for the purposes sold, and that it was fraudulent within the statute.

Now, this Act 126 absolves the purchaser of fraudulent fertilizer from having to pay for same; but the fertilizer was not in itself fraudulent, said the court, being an honest article of commerce and duly inspected by the official fertilizer inspector and found to conform to all the requirements of law. It did not accord with the representations which defendant said the sales agent made, but which the agent denied having made; but this did not render it fraudulent. The representations, if made, might have been fraudulent, without the fertilizer itself being so, said the court.

The contract called for "planters' cane fertilizer No. 8, 8 per cent ammonia," with nothing said as to the kind of ammonia. Moreover, it contained the clauses that the fertilizer "is purchased without any guaranty from the chemical company or its agents as to results from its use," and that "no agreement not expressed in this contract shall be binding" upon the company.

The company showed that "planters' cane fertilizer No. 8, 8 per cent ammonia" was manufactured according to advertised formula, was on the market as such, and that the article sold to Barton & Barton conformed to the formula.

Synopsis of Recent Chemical & Metallurgical Literature

Distribution of Phosphorus Between A_c and A_{c_1} .—J. H. Whiteley, of Stockton, England, read a very interesting and important paper upon this subject before the British Iron and Steel Institute May 6, 1920. Experimenting on steels listed in Table I, he found that after normalizing any of these at 1,300 deg. C. a uniform distribution of all elements which are affected by the copper reagent was had. If, now, one of these normalized samples, such as E, be heated for one hour at 810 deg. C. and then quenched, it would appear as Fig. 1 after etching with picric acid. The striated areas evidently represent the patches of martensite, and the light areas represent the patches of ferrite existing in equilibrium with austenite at 810 deg. C., which is within the transformation range for that steel. Etching with a copper reagent merely accentuates the contrast between light and darker areas.

The author recommends that a polished specimen, etched with picric acid, be repeatedly dipped in a reagent (containing 0.04 g. of copper oxide dissolved in 6.0 c.c. of strong nitric acid and made up to 200 c.c. with methylated spirit) until a bluish coating appears. Then remove the copper by rubbing the surface lightly with the finger under running water and repolish the surface on a wet cloth free of polishing powders. Repeated etchings bring out very delicate contrasts. Sharp contrasts can also easily be had by following one such etching with the usual Stead's reagent.

If Fig. 1 be heated *in vacuo* at 680 deg. C. for fifteen minutes, and etched with the copper reagent noted above, the structure shown in Fig. 2 is revealed at the same spot. Evidently, light areas represent location of alpha iron existing at 810 deg. C. poor in carbon and rich in some other element "X." If only carbon were responsible the dark areas in Fig. 2 would be smaller than in Fig. 1, rather than larger.

Similarly, quenching from various temperatures between A_c and A_{c_1} showed that a redistribution of "X" and carbon occurs at any temperature within the transformation range. The white areas naturally diminish relatively as the temperature rises, since the volume of austenite holding carbon in solution increases in volume with increasing temperature.

Figs. 3, 4 and 6 show the appearance of sample G, after various temperings at 740 deg. C. Since carbon has been shown to

diffuse very rapidly, "X" appears to require four hours to reach equilibrium at 740 deg. C. The same effect occurs quicker at higher temperatures, but in this case the white areas are smaller, due to a larger relative volume of austenite. Diffusion below A_{c_1} is very slow, since twenty hours at 660 deg. C. is required to give fuzzy edges on the white spots of Fig. 6.

By etching carefully to bring out relief in the dark areas, such as in Fig. 4, it was found that the diffusion of "X" is quite rapid in gamma iron. Uniform distribution of "X" in gamma iron requires only fifteen minutes at 840 deg. C., but even so is not as rapid in diffusion as carbon (Fig. 5).

When annealing above A_{c_1} , "X" diffuses very much slower, requiring 1,000 deg. C. before it reaches the rate attained at 860 deg. C. The author cites this as evidence that the martensites produced by quenching from temperatures a little below and a little above A_{c_1} are not physically identical.

Evidence that the white spots in Fig. 6 are really due to phosphorus was had by studying compositions of various steels. For instance, in sample A, after having been heated several hours at 820 deg. C. and etched, only the pearlitic areas and grain boundaries could be seen. Samples B and C, after one hour at 820 deg. C., gave the same appearances as steels D and E, but less pronounced, the gamma iron areas being etched less deeply.

If the white spots represent high P concentration in

Fig. 1. Sample E, 1 hr. at 810 deg. C. and quenched. $\times 420$.

Fig. 4. Sample G, after 1 hr. at 740 deg. C. $\times 400$.

Fig. 7. Sample G, after 1 hr. at 810 deg. C. and 15 min. at 740 deg. C. $\times 440$.

Fig. 2. Same as Fig. 1, tempered at 680 deg. C. for 15 min. $\times 420$.

Fig. 5. Sample G, after 1 hr. at 760 deg. C. and 5 min. at 830 deg. C. $\times 440$.

Fig. 8. Sample G, slowly heated to 830 deg. C. and held there 1 hr. $\times 400$.

Fig. 3. Sample G, after 15 min. at 740 deg. C. $\times 400$.

Fig. 6. Sample G, after 4 hr. at 740 deg. C. $\times 400$.

Fig. 9. Sample G, as rolled and 2½ hr. at 855 deg. C. $\times 135$.

TABLE I. ANALYSES OF SAMPLES USED IN THE EXPERIMENTS

No.	Description	C							Tempera- ture of Reversal, Deg. C.	Carbon Content of Gamma Iron at This Temperature Per Cent
		Per Cent	Si Per Cent	P Per Cent	S Per Cent	Mn Per Cent	Cu Per Cent	A Per Cent		
A	Basic open-hearth steel plate	0.11	0.04	0.006	0.023	0.29	0.012	0.004		
B	Basic open-hearth steel plate	0.155	0.025	0.01	0.027	0.48	0.083	0.10	810	0.35
C	Basic open-hearth steel plate	0.16	0.03	0.014	0.038	0.57	0.06	0.044	810	0.35
D	Basic open-hearth steel plate	0.18	0.04	0.027	0.039	0.45	0.054	0.065	780	0.45
E	Acid open-hearth steel plate	0.185	0.015	0.061	0.075	0.52	0.086	0.054	770	0.50
F	Basic Bessemer steel billet, 2-in. square sec- tion	0.06	tr.	0.104	0.112	0.56	0.026	0.022		
G	Basic open-hearth steel plate	0.18	0.04	0.12	0.055	0.51	0.067	0.026	740	0.75
H	Case-hardened electrolytic iron	0.20		0.002		none

alpha iron, then the percentage of phosphorus must be higher in low-carbon steel to show the same etching differences because they could contain a larger volume of ferrite—a consideration checked by experiment. Time, temperature and concentration affect the size and appearance of the white areas exactly as they should if they were due to some diffusible substance contained therein.

Analyses given in Table I make it clear that whereas the contrasts developed by the copper reagent vary directly with the phosphorus contents, none of the other elements show parallel differences. For instance, silicon is very low in all samples. Copper in samples B and G is about the same, yet there is a marked difference in etching effects. Manganese was absent in sample H and was present in quite considerable amount in sample A, yet the action of the cupric reagent is very similar. Samples B and G are about equal in manganese, yet the reagent brings out extreme differences. Copper in B is seven times as much as in A, yet the cupric reagent acts about the same in these cases. B, again, is higher than sample G in copper, whereas the latter shows pronounced contrasts under the reagent. As for arsenic, G contains one-quarter as much as B and A contains one-twenty-fifth as much as B, proportions which may not be harmonized with the experiments.

It is possible that "X" is some element not usually analyzed for. Mr. Whiteley notes that a $\frac{1}{2}$ -g. piece of G was heated four hours at 1,000 deg. C. in dry hydrogen, cooled in the furnace, then heated one hour at 840 deg. C. in dry hydrogen, a procedure thought to remove oxygen effectively, yet the resulting structure after etching was entirely similar to Fig. 6.

If samples are quenched after a long time near A_c , ferrite is likely to etch more quickly than the martensite, since the latter contains such high carbon that its solution pressure is less than the low-phosphorus ferrite. If this same sample is air-cooled, etching reverses, since then there is no cementite in solution. There is a temperature where the etching figures reverse, as tabulated under "Temperature of Reversal." This is evidently the temperature where the solution pressure of alpha iron containing P equals that of austenitic material. Phosphorus has been previously equalized by high-temperature normalizing; therefore it would require a diffusion and divorce of carbon and phosphorus to reverse these etching figures, since martensite otherwise would always etch less than iron containing no carbon in solid solution.

Fig. 7 shows small white spots locating high-phosphorus areas at 840 deg. C and white markings outlining the volume of ferrite existing at 740 deg. C. Phosphorus appearing in the lower temperature ferrite is coming from the surrounding black portion—that is, from gamma iron—more rapidly than from the en-

closed white portion. Phosphorus, as well as carbon, is more soluble in gamma iron at higher temperatures, but the solubility of phosphorus is less if the austenite is saturated with carbon at the high temperatures. Therefore phosphorus is not completely insoluble in gamma iron.

In all the experiments, small samples were heated very rapidly, requiring only two or three minutes. When heating at 4 deg. per min. above 700 deg. C., followed by air cooling, all the structures developed were the same up to 815 deg. C. Fig. 8 shows the cellular structure developed by slow heating and soaking at temperatures higher than 815 deg. C., then quenching or air-cooling. Time required to develop this structure varies inversely as the temperature above 820 deg. C. If the phosphorus has not previously been entirely equalized, cellular structure is found after a rapid heating. Soaking at high temperature and slow heating seems to be essential for cellular structure in previously normalized samples. Phosphorus is responsible for this phenomenon, because it could not be developed in sample A and increased in contrast and ease in formation as phosphorus increased. The temperature required to form the structure increases with the amount of carbon in the steel, consequently it can be developed only in steels of very low carbon contents. Much further work is required before these and other points in connection with the subject can be elucidated.

Micro-ghostlines shown in rolled plate by copper reagents have ordinarily been ascribed to phosphorus. That they remain after heat treatment has been explained by the slow diffusion of phosphorus, but it has herein been shown that phosphorus migrates rapidly within the transformation range. Samples A to E in their rolled condition were heated for two and one-half hours at temperatures slightly below A_c , which would certainly have equalized phosphorus in the gamma iron. Fig. 9 shows sample G after such heat treatment; ghostlines are still present. If rolled plate is heated slowly to 900 deg. C., a cellular structure is developed, but the cells are ranged parallel to the direction of rolling. It is therefore evident that the micro-ghostlines are not entirely due to the heterogeneous distribution of phosphorus. To account for these ghostlines it seems necessary to infer the presence of some other substance which diffuses with extreme slowness at temperatures below 950 deg. C., but with greater rapidity at 1,000 deg. C.

Reconstruction Status of the French Industries.—The official report of the French Industrial Reconstruction Bureau states that the activities in the devastated area are progressing quite satisfactorily. This, of all the plants in operation in 1914, employing 729,185 workmen, about 77 per cent were already in working condition July 1, 1920, employing 307,185 workmen. (*La Technique Moderne*, September, 1920.)

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Production of Chlorides of Zinc From Zinc Ores.—

A method of preparing zinc chloride and the double chlorides of zinc with the alkali metals from zinc sulphate is described by F. K. CAMERON, J. A. CULLEN and R. W. HYDE. The object of the invention is to obtain this salt by a simple and economical process from zinc ores. Zinc sulphate is prepared by roasting oxide ores of zinc with sulphuric acid and subsequently leaching the product. The resulting solution is treated for the removal of impurities. Sodium chloride is added in excess and the solution is evaporated to a density of about 55 deg. Bé. Upon cooling the concentrated solution sodium sulphate will crystallize out and can be separated from the mother liquid. The solution is concentrated to a density of about 60 deg. Bé. and upon cooling a double salt of the composition $\text{ZnCl}_2 \cdot 2\text{NaCl} \cdot 3\text{H}_2\text{O}$ will separate as pure crystals. In case insufficient sodium chloride was added the salt $\text{ZnCl}_2 \cdot \text{NaCl} \cdot 3\text{H}_2\text{O}$ will separate upon cooling. If to the double salt a solution containing 30 per cent or more hydrochloric acid be added and the mixture be agitated, sodium chloride will separate. The filtrate can be freed from hydrochloric acid by heating and upon evaporation pure zinc chloride can be obtained. (1,352,399; assigned to the American Smelting & Refining Co.; Sept. 7, 1920.)

Aluminum Casting Alloy.—THERON D. STAY, of Cleveland, Ohio, has found that an aluminum alloy containing 10 to 12 per cent copper and 0.1 per cent or less titanium is especially adapted for the production of castings in which the metal is irregularly distributed as to bulk, but which must possess good machining and bearing qualities. The process of making the alloy is divided into four stages: (1) The production of an alloy containing about 82 per cent copper, 12 per cent aluminum and 6 per cent titanium in an electric furnace, titanium oxide being reduced by an excess of aluminum; (2) the production of an alloy containing about 52.1 per cent aluminum, 46.5 per cent copper and 1.4 per cent titanium by melting 100 parts of the alloy made as in (1) and 100 parts of copper in a graphite crucible and adding to the molten metal 50 parts of an aluminum alloy containing 3 per cent copper; (3) production of an alloy containing equal parts of copper and aluminum in a crucible furnace, and (4) production of the desired alloy containing 88 to 90 per cent aluminum, 12 to 10 per cent copper and 0.1 per cent titanium or under, from proportional amounts of the alloys obtained in (2) and (3), aluminum and scrap alloy, melted in a crucible. By producing the final alloy in this way only a relatively small amount of alloy has to be produced in an electric furnace at a high temperature and a minimum amount of metal has to be heated to the high temperature necessary to melt copper. (1,352,322; assigned to the Aluminum Castings Co.; Sept. 7, 1920.)

Use of Sulphur Dioxide as a Reducing Agent in the Electrolysis of Copper Solutions.—In the electrolysis

of solutions obtained by leaching copper ores with sulphuric acid the current efficiency is decreased by the presence of ferric iron, ferrous iron being without appreciable effect, and the low current efficiency is one reason why hydrometallurgical processes are not extensively applied to copper ores. It is necessary, at plants in operation, to remove the copper from a portion of the solution by some other method than electrolysis, usually by precipitation on scrap iron, otherwise the accumulation of iron salts through the cyclic use of solution would make continued operation impossible. The copper-free solution is discarded and the resulting waste of acid adds to the cost of production. WILLIAM E. GREENAWALT, of Denver, Col., has designed an apparatus whereby sulphur dioxide is used as a depolarizer and reducing agent for ferric salts in the electrolysis of impure copper solutions containing iron. The application of sulphur dioxide to an electrolyte so that it will function effectively in reducing ferric salts produced by electrolysis and act as a depolarizer presents some difficulties. These are slight solubility of sulphur dioxide in water or copper solutions, particularly in hot solutions; its reducing action in cold solutions is slow but is effective in hot solutions. The slight solubility renders the effect transient. In the apparatus designed by Greenawalt a large volume of electrolyte contained in a closed tank is treated with sulphur dioxide by spraying the solution into sulphur dioxide gas by means of rapidly rotating disks, which also agitate the solution. A portion of the reduced solution is sprayed into a trough on the side of the closed tank from which it flows to the electrolytic cell. The rate of flow is such that the tailing solution from the cell contains less than 0.25 per cent ferric iron. The concentration of sulphur dioxide gas in the closed tank is maintained by a pyrites, sulphide concentrate or other burner. The gas passes in series through several reducing tanks and finally to a scrubbing tower which is fed with fresh solution from the leaching tanks. The solution from the tower flows to the first reducing tank. In the arrangement described there are two electrolytic cells for each reducing tank, a portion of the oxidized solution from the first pair of electrolytic cells is bypassed to the second reducing tank and so on. (1,353,995; Sept. 28, 1920.)

Alloys.—The following special alloys are described by FOSTER MILLIKEN of Lawrence, N. Y.:

An alloy to resist high temperatures and the action of acids, alkalis and chemical mixtures at high temperatures:

	Per Cent
Copper	50 to 60
Nickel	28 to 36
Zinc	4 to 8
Iron	4 to 8

An alloy designed for the manufacture of valves and fittings, particularly those used in handling gasoline and light petroleum distillates:

	Per Cent
Lead	10 to 14
Copper	55 to 65
Nickel	6 to 11
Zinc	14 to 18

Acid-resistant and high-temperature-resistant alloy:

	Per Cent
Iron	18 to 20
Chromium	5 to 7
Copper	31 to 38
Nickel	38 to 46
Manganese	1 to 2

(1,354,988; 1,354,989; 1,354,990; assigned to Foster Milliken, S. Fullerton Weaver and James M. Repplier, as trustees; Oct. 5, 1920.)

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Preparation of Phthalic Anhydride.—Phthalic anhydride is prepared by passing naphthalene vapor mixed with oxygen-containing gas—e.g., air—over an appropriate catalyst at a temperature below red heat, say 380 to 400 deg. C.; suitable catalysts are vanadium or molybdenum oxides. The catalyst may be prepared, for example, by impregnating pumice with a colloidal solution of vanadic acid mixed with starch or finely-divided blood charcoal, drying, and heating in air to burn off the carbonaceous matter; or by soaking pumice in gum solution, and then shaking it with ammonium vanadate; or powdered pumice is mixed with ammonium vanadate and suitably formed; or ammonium molybdate is precipitated on pumice by means of blood charcoal, and the charcoal then burnt off by heating in air. (Br. Pat. 145,071—1919. A. WOHL, Langfuhr, Danzig, Aug. 18, 1920.)

Hardening Metals.—The hardness and tenacity of metals, particularly aluminum and its alloys, and their ease of working with cutting tools are increased by heating for a considerable length of time to a temperature below the usual annealing temperature. An aluminum-zinc alloy with 15 per cent of zinc after being cast or annealed at 530 to 550 deg. C. is kept at 70 deg. C. for four or five days; an aluminum-copper alloy with 2 per cent of copper is kept at 160 deg. C. for ten days. Bronze with 6 per cent of tin is kept at 500 deg. C. for five days, and brass with 28 per cent of zinc is kept at 300 deg. for three days, or 210 deg. C. for ten days. Soft iron is kept at 300 deg. C. for fifty days. The heating may be interrupted during the process to enable the metal to be shaped, whereupon the heating is continued until the final hardness is attained. (Br. Pat. 145,129—1919. SOC. ANON. DES USINES GIULINI, Basel, Switzerland, Aug. 25, 1920.)

Printing Fabrics and Yarns.—Discharge effects are obtained by first mordanting cotton fabrics or yarns with tannate of aluminum, iron or chromium, then printing on a thickened solution of caustic alkali, to which may be added vat or sulphur dyes and a reducing agent, or an alkaline mordant such as sodium aluminate or an alkaline lead solution, or both, then aging or steaming, washing or otherwise preparing for dyeing, and finally dyeing with colors appropriate to the mordants used. The initial mordanting may be effected by first applying aluminum, iron or chromium mordants and then dyeing, padding or printing with tannin, or vice versa, or the metal salt and tannin may be applied simultaneously. Other colors—e.g., aniline black, vat or sulphur dyes—or diazo compounds (on fabric prepared with β -naphthol), or other discharges may be applied at the same time. Glucose, glycerine or tannin may be added to the alkaline discharges. According to examples—fabric is chrome-mordanted, tanned, printed with the alkaline discharge, aged, washed and dyed; fabric is padded with a solution of tannin and potassium chlorate, padded with iron acetate, printed with the alkaline discharge, aged, washed and dyed; fabric is printed with a mixture containing iron acetate, tannin, acetic acid, hydrosulphite N F conc. and starch-dragon thickening, aged, washed and soaped, printed with the alkaline discharge, aged, washed and dyed; fabric is padded with a solution of tannin and potassium chlorate,

printed with iron acetate and aluminum acetate simultaneously, aged, washed and soaped, printed with the alkaline discharge, aged, washed and dyed. (Br. Pat. 145,240—1919. CALICO PRINTERS' ASSOCIATION, Manchester; W. ROUSE, Renfrew and G. NELSON, Hyde, Cheshire, Aug. 25, 1920.)

Scouring Wool.—Raw wool, woollen yarns and cloth, and mixed goods are scoured, etc., by treatment with the alkaline salts of acids of the type of lysalbinic and protalbinic acid, to which cleaning material such as ammonia salts, sodium carbonate, potassium carbonate and soap may be added. The wool, etc., may be scoured at a temperature of 70 deg. C. The first-mentioned alkaline salts are prepared by heating albuminoid matter in alkaline solution—for example by heating glue in a solution of caustic alkali to 80 or 85 deg. C. for from two to three hours—neutralizing the solution with weak formic acid, and then concentrating the solution. Impurities may be removed by treating with dry calcium or magnesium hydroxide, or both, filtering, and then adding sodium carbonate. (Br. Pat. 145,448—1919. C. BENNERS, Grunau, near Berlin, Aug. 25, 1920.)

Sulphuretted Dyes.—Sulphuretted dyes are obtained by heating with sulphurizing agents mixtures of aminoazo, diaminoazo, nitroaminoazo, nitrooxyazo, or aminoxyazo compounds with (α -alkylated diamines of the benzene or naphthalene series, for example *m*- or *p*-toluylenediamine or xylylenediamine, or *N*-aryl-derivatives of such diamines, for example naphthyl-*m*-toluylenediamine, or the corresponding nitroamines. According to examples products are obtained by heating with sulphur mixtures of *m*-toluylenediamine with aminoazobenzene, benzene-azo- β -naphthylamine, benzene-azo- α -naphthylamine, *p*-nitrobenzene-azo- α -naphthylamine, or *p*-nitrobenzene-azo- β -naphthylamine, and a mixture of 4- α -naphthylamino-2-aminotoluene with benzene-azo- α -naphthylamine. The products are solubilized by treatment with sodium sulphide and dye cotton olive, reddish-brown, brown, yellow-olive, yellowish-brown, and brown to black brown shades. Products are also specified from mixtures of *m*-toluylenediamine with *p*-nitrobenzene-azo-*m*-toluylenediamine (brownish orange), benzene-azo-*m*-phenylenediamine (black brown), *p*-nitrobenzene-azo-cresol (crude cresol mixture), a benzene-azo-phenol, or a benzene-azo-naphthol. (Br. Pat. 145,523—1920. AKT. GES. FÜR ANILIN FABRIKATION, Treptow, Berlin, Sept. 1, 1920.)

Cellulose Acetate.—Cellulose acetate soluble in acetone is dissolved in a fully hydrogenized monocyclic ketone such as cyclohexanone or methylcyclohexanone, to form solutions suitable for lacquering and for the production of artificial silk and films. A solvent or diluent, as for example, alcohol, acetone, ethyl acetate or benzene, may be added to the ketone. (Br. Pat. 145,511—1919. RADISCHE ANILIN UND SODA-FABRIK, Ludwigshafen-on-Rhine, Sept. 1, 1920.)

Sulphuretted Dyes.—Sulphuretted dyes are obtained by heating with a sulphurizing agent the azo compounds prepared by coupling diazo compounds with *N*-ethylarylamines; aromatic amines or substances yielding them such as nitroamino or azo compounds may be added to the melt. According to examples products are obtained by heating with sulphur *p*-nitrobenzene-azo-ethyl- α -naphthylamine, *p*-aminobenzene-azo-ethyl- β -naphthylamine, *p*-aminobenzene-azo-ethyl- β -naphthylamine, a mixture of benzene-azo-ethyl- α -naphthylamine and ben-

zidine, a mixture of benzene-azo-ethyl- α -naphthylamine, and benzene-azo- α -naphthylamine, or a mixture of *p*-nitrobenzene-azo-ethyl- α -naphthylamine and *m*-toluylenediamine. The products are solubilized by treatment with sodium sulphide, and dye cotton yellow-brown and brown-yellow shades. (Br. Pat. 145,522—1919. AKT. GES. FÜR ANILIN FABRIKATION, Treptow, Berlin, Sept. 1, 1920.)

Edible Gelatine.—Edible gelatine is prepared in sheet form by applying a coating of liquid gelatine to a flexible foundation from which when dry the coating is stripped as a sheet, and finally, in order to simulate the crinkled appearance of ordinary edible gelatine, placing the sheets in a frame of wire netting, softening by momentary immersion in hot water, and redrying while in the frame, for example, in the current of air from a blower. (Br. Pat. 145,486—1919. R. A. MCQUITTY, London, Sept. 1, 1920.)

Treating Cellulose and Its Products.—Pure cellulose such as cotton, cellular tissue and papers and cardboards made therefrom are hardened and rendered water-resisting by treatment with thionyl chloride. Indifferent solvents for the thionyl chloride, such as chloroform, carbon tetrachloride, benzene, etc., may be used. A better parchenting effect on paper is produced by exposing the paper, after treatment if necessary in vacuum, to the vapors of thionyl chloride. Continued treatment renders paper absolutely impermeable. It is desirable, after treatment, to wash with water or dilute alkali, or to treat with dry ammonia gas. (Br. Pat. 145,610—1919. F. MOELLER, Cassel, Germany, Sept. 1, 1920.)

Treating Cellulose and Its Products.—The process described in Br. Pat. 145,610—1919 may be applied to the treatment of vegetable materials containing cellulose, such as wood, cork, straw, jute, hemp, linen, flax, artificial silk, yarns and fabrics obtained therefrom, cellulose derivatives such as cellulose hydrate, hydro-cellulose, oxy-cellulose, kindred substances such as starch, dextrine, or fabrics and substances treated or impregnated therewith. These materials may also be hardened and rendered less sensitive to water by treatment with sulphur chloride, the deposited sulphur being subsequently removed by a suitable sulphur solvent. The products of this treatment may be parchmented and the fat-resisting material so obtained rendered water-repellant by further treatment with thionyl chloride. (Br. Pat. 145,611—1919. F. MOELLER, Cassel, Germany, Sept. 1, 1920.)

Coated Fabrics.—In the production of coated fabric for balloons, etc., the elasticity and softness of the fabric are retained by impregnating with a pliable medium, such as castor oil or a solution comprising softening agents, previous to the application of the coating of nitrocellulose, etc., thereby limiting the penetration of the coating material into the fiber of the fabric. (Br. Pat. 145,546—1919. GES. FÜR VERWELTUNG CHEMISCHER PRODUKTE, Berlin, Sept. 1, 1920.)

Cellulose Acetates.—The acetylation of cellulose or its derivatives is carried out in two stages: In the first stage a catalyst other than sulphuric acid is employed, or several of such catalysts either simultaneously or in succession, and in the final stage sulphuric acid is used as the catalyst. Working in this way, complete solution of the cellulose is obtained, and the acetates can be separated from the solutions by dilu-

tion with or in the presence of acetone; the solubility of the acetates may be varied by subjecting them in the known way to a process of hydrolysis. In examples, bromine and fused zinc chloride are used as catalysts in the first stage, and acetylation is completed after the addition of sulphuric acid diluted or not with glacial acetic acid and with or without a further addition of acetic anhydride. (Br. Pat. 145,525—1919. AKT. GES. FÜR ANILIN FABRIKATION, Treptow, Berlin, Sept. 1, 1920.)

Compound Sheet Materials.—A method of uniting two or more layers of dissimilar materials, particularly plastic materials, which are difficult to stick together—for example, uniting rubber with other plastic materials—consists in providing a suitable intermediate layer to which the layers to be connected firmly adhere. Materials suitable for the intermediate layer are pulverulent materials such as straw meal, wood meal, barium sulphate, talc, china clay, vegetable powders, etc., or fibrous materials such as textile fibers, cellulose fibers, wadding, fiber fleece, etc., or a layer of paper or wide-meshed fabric. For example, a gas-proof and liquid-tight fabric may be prepared by coating a fabric foundation with acetyl-cellulose as a gas-proof layer, then applying the intermediate layer before acetyl-cellulose is completely dry; and finally applying a liquid-tight layer of nitrocellulose. (Br. Pat. 145,544 1919. GES. FÜR VERWELTUNG CHEMISCHER PRODUKTE, Berlin, Sept. 1, 1920.)

Degumming Textile Materials.—In an amyolytic process for degumming textile materials, such as fabrics, a bath which may be prepared from ordinary hard water is employed containing animal amylase, neutral salts of alkali or alkaline-earth metals such as sodium or calcium chloride, and biliary salts, whereby the amylase is protected, and the bath may be used at a temperature of 58 deg. C. (Br. Pat. 145,583—1919. SOC. SUISSE DE FERMENTS, Basel, Switzerland, Sept. 1, 1920.)

Oxyaldehydes.—Oxyaldehydes are prepared by the reaction of phenols or their derivatives with formaldehyde, or a compound yielding it, in the presence of a nitroso compound and an acid condensing-agent. Examples are given of the preparation of salicylic aldehyde and *p*-oxybenzaldehyde, 2-oxy-5-methylbenzaldehyde, anisic aldehyde, vanilin, protocatechuic aldehyde, and the aldehyde from 2-naphthol-3:4-disulphonic acid; the nitroso compounds specified are nitrosodimethylaniline, nitrosodiethylaniline, and nitrosophenol, hydrochloric acid being employed as condensing-agent. (Br. Pat. 145,581—1919. AKT. GES. FÜR ANILIN FABRIKATION, Treptow, Berlin, Sept. 1, 1920.)

Damp-Proof Matches.—A process for making damp-proof matches consists in using in the paste from which the heads are formed an agglutinating substance formed by the condensation product of a mixture of substances having the properties of phenol and of an aldehyde. These substances react when heated and produce, in the presence of suitable catalyzers, insoluble bodies. For example, a paste is prepared by placing the powdered constituents in a bath containing water, phenol aldehyde and soda, the stalks are dipped into this bath and after removal the tips are allowed to harden. The aldehyde and the catalyzer, which may be hydrochloric acid, may be used in the form of vapor. (Br. Pat. 145,798—1919. R. DUBRISAY, Paris, Sept. 1, 1920.)

Current Events

in the Chemical and Metallurgical Industries

The Perfume Industry of France

On Friday evening, Nov. 12, Burton T. Bush, president of Antoine Chiris Co., addressed the American Section of *La Société de Chimie Industrielle* on the natural perfume industry of France. Excellent views of the flower fields near Grasse and interiors of the attar extraction factories were exhibited on the screen. Three processes of extraction were illustrated:

Enfleurage, or the cold fat process, is the oldest. The blossoms are packed in layers with soft tallowd cloths between, the attar vapors being adsorbed, giving the odorous pomas from which the cologne spirit perfumes are prepared.

Maceration, or the hot fat process, is used where heat does not injure the essential oils. The blossoms are ground up and cooked in molten fats heated by hot water and pomas made much more rapidly than in the cold process.

Countercurrent extraction with pure petroleum ether is the latest method, giving a high rate of production and low-temperature extraction. Concretes, a solution of the attars in the natural blossom waxes, are produced.

Only about 11 oz. of substance is obtained from 100 lb. of such a flower as lavender. Last year 121,000 lb. of violets, 1,200,000 lb. of roses and 500,000 lb. of bitter orange blossoms were extracted. The demand for cosmetic odors cannot be supplied by the natural industry, with the result that synthetic products are now being produced in great quantities. In the United States, 36,000 lb. of ionone (synthetic irone or extract of violet) was manufactured last year. Mr. Bush expressed the opinion that if this industry is given tariff protection, it will grow greatly.

Annual Meeting of American Ceramic Society

The 1921 annual meeting of the American Ceramic Society will be held Feb. 21 to 24, at Columbus, Ohio, where the Hotel Deshler has been engaged as headquarters. The management of this new and commodious hotel has promised to reserve the ball-room and four other rooms on the same floor, so that the general meetings of the society and the divisional meetings will be taken care of adequately.

Details of the entertainment are in the hands of the local committee, of which Prof. A. S. Watts is chairman, and it is expected that the usual Section Q, or smoker, will take place on Monday night, with the banquet on Tuesday. Those who recall these delightful events at the Philadelphia meeting will not fail to be present this year.

The trips to be taken on the last day of the meeting will be replete with interest, as Columbus is situated at the very heart of the clay-working industry.

The literary program, if it may be judged by past experience, will be filled with papers of a high degree of excellence. The arrangement of the program is in charge of R. H. Minton, chairman of the Committee on Papers, and contributors should communicate with him.

New Jersey Chemical Society Holds Third Annual Meeting

The third annual meeting of the New Jersey Chemical Society was held at Newark Monday evening, Nov. 8. Thirty-three new members were elected at this meeting, thereby making a total membership for the society of 516.

Richard K. Meade¹ gave an illustrated talk on the manufacture of lime and hydrated lime, emphasizing the different types of furnaces used, the various methods of firing, and the products produced.

James A. Donan, a representative of the Standard Oil Co. of New Jersey, accompanied the moving pictures depicting "The Story of Petroleum Oil," by an address in which he explained and elaborated on the pictures, describing the production of oil and its byproducts from the oil well to the consumer.

E. E. Klipstein, who was to talk on "Prospective Competition Between European and American Chemical Industries," was unable to be present, and his place was taken by Dr. R. S. Lee, who gave an extremely interesting illustrated lecture on the yeast industry.²

National Council of State Boards of Engineering Examiners Formed

Representatives from seven state boards of engineering examiners—Colorado, Michigan, Iowa, Florida, South Dakota, Louisiana and Illinois—met in Chicago Nov. 8 and 9 and organized the National Council of State Boards of Engineering Examiners.

The purpose stated in the constitution as "to examine the state laws providing for registration of engineers and the custom and rule of procedure of the different boards in the examination of applicants, with suggestions and recommendations for uniformity of practice so far as the same can legally be done by the different state boards, and to provide for reciprocal relations between the state boards for granting registration licenses to applicants from other states on equal terms of examination."

The officers elected were: President, Marcel Garaad, New Orleans; vice-president, C. S. Hammatt, Jacksonville, Fla., and secretary-treasurer, Alvin Le Van, Des Moines, Iowa. The next meeting will be in St. Louis, Oct. 3, 1921.

Bureau of Mines Station at Rolla, Mo.

Bureau of Mines representatives are touring the Wisconsin zinc district and the Missouri lead and zinc districts investigating various conditions connected with the location of the new Mississippi Valley zinc and lead station at Rolla, Mo. Among other members of the party were Frederick G. Cottrell, director of the Bureau; Charles Fulton, president Missouri School of Mines, and H. A. Buehler, State Geologist of Missouri.

¹See CHEM. & MET. ENG., "The Manufacturing of Lime for Chemical and Metallurgical Purposes," vol. 23, Nos. 17, 18, 19, pp. 841, 873 and 923.

²See CHEM. & MET. ENG., vol. 23, No. 17, pp. 835-837.

American Coke & Chemical Co. Begins Operating the St. Louis Plant

The St. Louis Coke & Chemical Co., subsidiary of the American Coke & Chemical Co., has heated the first forty ovens and blast furnace and will start the second bank of forty ovens within the next six weeks. By Dec. 1 the plant will produce from 100 per cent Illinois coal metallurgical coke for the blast furnaces, tar, gas for the steel mills of the National Enamelling & Stamping Co., ammonium sulphate, light oils and pig iron. The conversion of Illinois coal is made possible by the Roberts coke oven, invented by Arthur Roberts, an American.

The American Coke & Chemical Co., of 208 South La Salle St., Chicago, controls subsidiary companies in several states, all licensed under the Roberts patents. Work will be started in Chicago this winter on the first unit of 320 ovens, the plant to be laid out for the eventual construction of 1,500 ovens. Plants of 80 ovens will be started in several other places in the early spring.

The Roberts process is said to be the first successful method for the coking of coals such as are mined in Illinois. The original test was run in the 24-oven plant at Dover, Ohio, where 16,000 tons was put through. The coke was used to produce pig iron at the plant of M. A. Hanna & Co. and the pig was reduced to steel plates at the Niedringhaus plant, Granite City, Ill. These plates after passing all Government tests were shipped to the Pacific Coast, where they were used in the construction of Hull No. 18 of the United States fleet.

The inventor states that the reasons for the excellent performance of this oven, as compared with other processes attempting to coke soft coals, is due to the absolute control of the heat. The heat is generated uniformly on all surfaces and not at concentrated points. The distribution of heat is even and in large volume as distinguished from high temperatures existing in other ovens. Short coking time and low temperature are accomplished by special construction which permits the large volume of heat in contrast to high temperatures now obtaining in narrow coking chambers. For these reasons superiority is also claimed in converting the regular coking coals.

Representatives of foreign business concerns are interested in this new American process. Japan can now coke only about one-half of 1 per cent of the coal mined; the Saar Basin and Lorraine coals have never been coked; only 10 per cent of the British coals are convertible and only 5 per cent of the United States coals are at present cokable. South America, Russia and other countries may be likewise benefited by the new process.

A.C.S. Intersectional Meeting

The Milwaukee and Chicago sections of the American Chemical Society will meet in joint session at Milwaukee on Nov. 20. Among the features of the occasion will be an indoor baseball game between teams of the two sections. The meeting originated on invitation from the Milwaukee Section. The social interchange between Western groups in the American Chemical Society promises to become contagious, causing a closer welding of all the parts into a better national organization.

St. Lawrence Waterway Hearings Under Way

The series of hearings before the International Joint Commission, which will be held in all the principal cities affected by the Great Lakes-St. Lawrence waterway project, was initiated in Chicago recently. Evidence was presented to show that:

1. The interior of the country—richest in productivity—is to a large extent the present and will be the future origin of America's export shipments.

2. This same section, by reason of its growing population, is to a large extent today and will be to a greater extent tomorrow the market for America's imports.

3. The need of more adequate means of ingress and egress from the central section of the United States and Canada to the markets of the world is America's greatest economic problem.

4. Increasing cost and difficulties of rail transportation from Atlantic seaports are placing a burden on commerce that is becoming prohibitive.

5. This waterway improvement comprising the completion of a route up the St. Lawrence from Quebec through Lake Ontario, the Welland Canal, Lake Erie and via Detroit to the whole system of the Great Lakes, costing about \$110,000,000, will provide the necessary facilities.

The Canadian section of the work will cost about \$60,000,000 and the international section about \$50,000,000. It is estimated that about 4,000,000 electrical horsepower would be developed in the system.

Compression and Hardness of White Metal Bearing Alloys

Experimental work on determining the compression and hardness value of white metal bearing alloys at temperatures up to 100 deg. C. has been completed by the United States Bureau of Standards. A paper has been prepared entitled, "Some Properties of White Metal Bearing Alloys at Elevated Temperatures," a summary of which is as follows:

An apparatus is described for determining the yield point and ultimate strength of white metal bearing alloys at temperatures up to 100 deg. C. A new design of heating apparatus is described for determining the Brinell hardness of such metals in the range of temperature indicated above. The results of compression tests and Brinell hardness tests at temperatures up to 100 deg. C. are given for five typical white metal bearing alloys, including three tin base alloys, one lead base alloy and one intermediate alloy. These tests showed that the tin base alloys maintain their properties better at elevated temperatures than those containing lead. Results of tests are given which indicate that up to 3 per cent the lead in a high-grade babbit does not affect the yield point or ultimate strength at 25 deg. C. or 75 deg. C. Tests are described which show that the yield point of tin base alloy is not affected by heating for six weeks at about 100 deg. C., but that the yield point is lowered in the lead base alloy by heating for only two weeks at this temperature.

Strong Paper Co. Changes Name

The Strong Paper Co. of Middletown, Conn., has changed its name to the Elam Strong Paper Co., and has increased its capital stock from \$100,000 to \$160,000.

New Forestry Policy Sought by the A.P.P.A.

A new forestry policy was recommended in the reports read at the American Pulp and Paper Association, which recently met in Chicago. It is said that the Federal Government is preparing to spend \$50,000,000 on forestry in the next five years in addition to large amounts to be expended by individual states.

The reports urge acquisition by State and Federal Governments of forest land and land for reforestation. Extension of federal supervision of state and private forests and a unified system of reforestation under federal control are also advocated.

To stop the cutting of young timber to pay taxes it was proposed that no state or federal taxes be collected on forest land until cutting of the timber started and that the tax then be placed on the lumber.

President George W. Sisson of the association said the paper industry is "in a better situation than many others because it had not been through a period of overproduction which piled up excessive stocks."

"On the contrary," he continued, "the mills have been barely able to keep up with the flood of orders. Our great problem is now and will continue to be the securing of a sufficient supply of raw material to meet the needs of the mill."

Fermogas Promoter Held for Grand Jury

Legal action has been brought against P. J. Chasler of 1259 51st St., Brooklyn, N. Y., for the alleged misappropriation of funds given him for investment in the Fermogas Co. This company has a small demonstration plant in which the Chasler process of fermenting cellulose to alcohol by means of a mold is shown to prospective stock purchasers. The claim is made that gasoline substitute can be produced and sold at a profit at 5c. a gal. The process has been examined by many investors and about \$70,000 worth of stock has been sold. However, there does not appear to be any technical proofs or recognized alcohol engineers' reports available to verify the claims of the inventor. The complaint was filed by Emmerick Bares, who bought \$5,000 worth of stock. Mr. Chasler was held under \$10,000 bail to await action of the Grand Jury.

E. A. Cappelen Smith Recipient of Gold Medal

At the meeting of the Mining and Metallurgical Society held at the Hotel Commodore, New York City, E. A. Cappelen Smith was awarded the society's gold medal for his excellent work in hydrometallurgy. Mr. Smith, who originally came to this country from Norway as a metallurgist, followed his profession here with the Anaconda Copper Co. and later with the Chile Copper Co. It was while connected with the latter company that he carried successfully to solution the problem of reclaiming copper from the great Chiqui-camata orebody in Chile by leaching and subsequent electrolytic deposition of copper.

The medal was presented by Waldeman Lindgren, president of the society, and speeches were made by Dr. Arthur L. Walker and Harry F. Guggenheim.

Shortage of Crude Oil Closes Plant

The Imperial Oil Co. has had to close its refinery at Ioco, near Vancouver, because it is unable to obtain crude oil, and consequently cannot renew contracts for fuel oil. The refinery will be reopened in June.

No Quarters for Civilian Chemists at Edgewood Arsenal

The War Department has ruled definitely that no quarters for civilian chemists may be erected at Edgewood Arsenal with War Department funds. The decision was based on the ground that the War Department could not depart from its policy of furnishing quarters to officers only. It is feared that this decision will have the effect of decreasing efficiency at Edgewood Arsenal, since its isolated location makes it necessary for the technical employees to live in Baltimore, which is forty minutes away. The train schedule is such that men who would be inclined to work overtime cannot do so.

Enlarging Iron Articles

In CHEMICAL & METALLURGICAL ENGINEERING for Sept. 1, 1920, a brief abstract of a paper read before the British Institution of Automobile Engineers was printed. It noted that it was commercially possible to deposit electrolytic iron on worn parts of machinery, to build them up to approximate size so that they can be carburized and machined to a piece practically as good as new. It should have been pointed out that the process was originated in Sherard Cowper-Coles' laboratory at Sunbury-on-Thames, and was largely used for the repair of worn parts of motor cars during the war.

Book Reviews

ADVERTISING THE TECHNICAL PRODUCT. By *Clifford Alexander Sloan*, vice-president Campbell-Ewald Co., and *James David Mooney*, vice-president staff General Motors Corporation. 365 pp., with illustrations and charts. New York: McGraw-Hill Book Co., Inc. Price \$5.

Prepared jointly by an engineer and advertising man collaborating with several authorities in both fields, this work is valuable for study and reference to the buyer and seller of advertising space alike, as well as to those who have technical products for sale and must plan selling campaigns. It is a clear analysis of the important factors peculiar to advertising the technical product. Many an advertiser can save considerable money now being wasted through lack of attention to the forces governing his selling plan. The salesman of space, on the other hand, will see in reading the text and between the lines that he must study to present the facts bearing on the economic returns to the advertiser and should not rely on the too common form of "good fellow" salesmanship. The principles laid down in this book may well be applied to general advertising procedure.

The authors have done well in dealing with cold facts and principles in contrast to the "pep" talk so commonly found in volumes on advertising and selling. The style and text matter in the first chapters make for interesting reading, the final chapters and appendix being largely a collection of data evidently gathered from reliable sources. It is a book for continued reference. Even those who feel they have graduated from the school of study may crystallize ideas and derive inspiration for fresh thought in its use.

Some parts of the text drag slightly, but the amount of superfluous matter is surprisingly small. The authors strike a false note once or twice in apologizing for reference to certain publishers of trade papers and journals. The open-minded reader would not take issue over these references or feel any stigma attached to sources of data, and the opinion of the superficial, suspicious reader doesn't matter.

CHESTER H. JONES.

Personal

Dr. WILDER D. BANCROFT, professor of chemistry at Cornell University, delivered an address before the Chicago Section of the American Chemical Society on "Contact Catalysis" on Nov. 6. The Chicago Chemists' Club gave a special luncheon for Dr. Bancroft at noon the same day. Dr. Bancroft also spoke before the students at Chicago University and Northwestern University the following week on "Colloids" and "Drops, Bubbles and Grains."

Captain D. B. BRADNER, acting director of research at Edgewood Arsenal, has resigned his commission and will continue his duties as a civilian.

ARTHUR HOWE CARPENTER has accepted the position of assistant professor of metallurgy at the Armour Institute of Technology, Chicago, Ill.

RICHARD H. CATLETT has resigned as production manager of the Taylor Chemical Co., Penn Yan, N. Y., to be chemical engineer with the Lewis Recovery Corp., Boston, Mass.

SIDNEY CORNELL will be engaged in professional work in Philadelphia for some time to come and can be addressed at 28 Cliveden Ave., Glenside, Pa. Mr. Cornell still retains his New York office at 80 Maiden Lane.

W. A. DEAN has resigned from the technical staff of the Dorr Co., New York, and has accepted a position as manager of the Gulf Reduction Co. His post office address will be Camp Walton, Fla.

SHERMAN EATON, who was formerly with the Wharton Steel Co., Wharton, N. J., is now with the Continental Clay Co., Langley, S. C.

Colonel C. W. EXTON has been transferred from the Infantry to head the training section of the Chemical Warfare Service. Colonel Exton, in addition to having been graduated from West Point, has been through the service schools of Fort Leavenworth and recently was graduated from the General Staff College. During the war he was Commandant at the service schools in France, in which emergency Chemical Warfare officers were among those trained.

ALBERT H. FAY is now valuation engineer, Oil and Gas Section, Internal Revenue Bureau, Washington, D. C.

LOUIS J. GUREVICH, research metallurgist, research department, Hydraulic Steel Co., Cleveland, Ohio, has been transferred in like capacity to the Canton Sheet Steel plant of the same company at Canton, Ohio.

A. L. HEILBRUNN of the Fleischmann Yeast Co., Chicago, spoke before the Chicago Chemists' Club recently on "Industrial Fermentation."

RAYMOND M. HOWE, of the Mellon Institute, spoke at the regular monthly meeting of the Pittsburgh Foundrymen's Association at the Hotel Chatham, Pittsburgh, Nov. 15. Mr. Howe spoke on refractories, with special reference to their application in foundry practice.

WALTER LAIB, who has been with the Ohio Salt Co., Rittman, Ohio, for nine and a half years as chief chemist and general superintendent, has resigned to assume the position of treasurer and sales manager of the Cleveland Match Co.

ROBERT J. MCKAY, superintendent of the research department of the International Nickel Co., of Bayonne, N. J., is now industrial fellow at the Mellon Institute, Pittsburgh, Pa.

Miss JESSIE E. MINOR, who has been for several years the chief chemist for the Hamersley Manufacturing Co. of Garfield, N. J., has recently moved to Springfield, Mass., to take charge of the pulp and paper department of the Emerson Laboratory at 145 Chestnut St. Miss Minor was for several years a graduate student at the University of Pennsylvania and later studied at Bryn Mawr, where she received the degree of Doctor of Philosophy in chemistry. She also spent several years studying industrial conditions in the Union of South Africa.

HARRY S. MULLIKEN has been engaged by the Bureau of Mines to act as special technical assistant to Director F. G. Cottrell. Mr. Mulliken's appointment puts into effect a plan which has long been considered of having a technical engineer attached directly to the office of the director. Mr. Mulliken is a graduate of the Worcester Polytechnic Institute. He began industrial metallurgical work with the Chicago and Aurora Smelting & Refining Co. He has since served as superintendent of the Pilot Bay, B. C., lead smelter; assistant superintendent of Gregg Refineries at Perth Amboy, N. J.; superintendent of the Aguascalientes Smelter of the American Smelting & Refining Co.; general superintendent of the Peñoles Co., at Mapami; superintendent of the American Metals Co., in Mexico. During recent years Mr. Mulliken has been practicing as a consulting engineer, with offices in New York.

BERT RUSSELL, who left the Patent Office a little over a year ago after extended service in its various chemical divisions, will, on Dec. 1, 1920, leave the service of Prindle, Wright & Small, New York City, to accept employment in the office of Roy F. Steward, chemist and patent attorney, McLachlan Bldg., Washington, D. C.

H. A. SCHWARTZ has become manager of research for the National Malleable Castings Co., Cleveland, Ohio.

LEWIS B. SKINNER, chemical and metallurgical engineer, of Denver, Col., is now connected with the Midwest Refining Co.

E. A. CAPPELEN SMITH has been awarded the gold medal of the Mining and Metallurgical Society of America for distinguished contributions to hydrometallurgy.

ARTHUR H. SPURLOCK, formerly of the American Refractories Co., has become treasurer, in charge of finances, accounting, credit, collections, etc., of the H. H. Robertson Co., Pittsburgh, Pa.

Dr. WILLIAM H. WALKER, after twenty-five years of active service in teaching and research in applied chemistry and chemical engineering at the Massachusetts Institute of Technology, has tendered his resignation as director of the division of industrial co-operation and research, to take effect on Jan. 1, 1921. He will resume his consulting practice which was interrupted in 1917 by his entering the service, and although no longer officially connected with the institute, will maintain his interest in the development of the division and will closely co-operate with it in the fulfillment of the contracts under the Technology Plan already existing. This division acts for the Institute of Technology in the administration of its obligation incurred under the Technology Plan by which over 200 of the most prominent industries of the country have made contracts involving annual retainer fees of over a quarter million dollars. Dr. Walker will be succeeded by Prof. Charles L. Norton, professor of industrial physics at the institute and director of the Research Laboratory of Industrial Physics.

Current Market Reports

The Chemical and Allied Industrial Markets

New York, Nov. 15, 1920.

Consumers have not lent active support to the chemical market during the week. Some trace of an irregular buying movement was inaugurated, but the punch has been lacking and operations were not impressive. There are many different opinions as to when a resumption of live trading will be noticed and even the best informed find it quite impossible to make any definite prediction, since no parallel situation has ever been witnessed before in the chemical market. Export orders reached the market in moderate quantities, principally for heavy chemicals to Europe. *Formaldehyde* prices were greatly depressed by large resale offerings and the market drifted into new low territory. Final quotations ranged from 24c. to 25c. per

lb. Small lots of *borax* are being moved at 9½@10c. per lb., according to time of delivery and quantity. Sales of brown, broken *acetate of lead* are reported by producers at 15½c. per lb., while white crystals are moving at 15@15½c. per lb. The inquiry is reported fairly active and supplies show no signs of accumulation in any direction. dealers offer carlots of powdered *sodium bisulphite* at 6½c. per lb. and 7c. in smaller quantities. This chemical has been in rather limited supply of late, but seems to be getting in better shape for prompt delivery. *Nickel salts* has been a surprise to local consumers, who expected a decline. Leading producers have not altered former quotations and are holding the single variety at 16c. per lb., and the double at 14c. per lb. *Barium chloride* has been reduced by leading holders, owing to the large supplies that were recently imported from Europe. Ton lots have changed hands as low as \$85 per ton. This seemed to be an inside figure and the general quotations heard range from \$90 to \$95 per ton.

COAL-TAR PRODUCTS

Buying of a very conservative order is still in evidence in practically all branches of the coal-tar market, with orders directed entirely to the present consumption. In producing quarters most factors realize the quiet conditions, but find sufficient business to keep plants in fair operation. Bituminous coal supplies and prices are reported quite favorable and tend to a steady production of crude by-products. *Aniline oil* retains its easy tendency, with the demand very light and supplies available in first hands at 27@30c. per lb. depending upon quantity. Leading factors in *benzaldehyde* report sales limited to small lots, with prices ranging for the technical grade at 65@70c. per lb. and U.S.P. at \$1@1.50 per lb. *Paratoluidine* remains quite firm in the hands of producers. The demand is sufficient enough to keep prices steady at \$1.85 per lb. *Xylene* is heard only in light routine demand and prices range from 45c. to 50c. per gal. *Napthalene* is meriting more interest among intermediate manufacturers and contract prices over next year are heard at 14c. per lb. Very little business is being turned at this figure and consumers are keenly looking forward to more normal prices.

SODIUM SALTS OVER 1920

The beginning of 1920 was the signal for a sharp impetus to all *sodium salts*. Reports from leading producers of an acute coal shortage brought *bichromate of soda* to the front with smashing advances ranging from 18c. per lb. in January to 45c. per lb. quoted in April, its brightest month. *Caustic soda* began its gradual climb during January and reached its peak in April. The incessant demand from all parts of the world, together with the abnormal railroad conditions, brought about a severe shortage on spot markets and domestic consumers were forced to pay a premium from second hands. *Soda ash* followed in sympathy with *caustic soda*. A novel feature of the market was the sensational rise of *nitrite of soda* from 14c. per lb. to 50c. per lb. Domestic manufacturers were hampered by a shortage of *soda ash*, one of the main constituents in its production, and importations were almost at a standstill. During March, 1920, a shipload of *nitrite* was ruined by an explosion and within forty-eight hours the price advanced from 15c. per lb. to 50c. per lb. All other *sodium salts* listed here have followed suit with the leaders due to the vast accumulation of export orders on the American market. Prices since June, however, have gradually been declining to a normal basis. Depreciation in foreign exchange, ample supply of coal, more stable conditions in railroad transportation and keener competition have brought prices back to a pre-war situation. Manufacturers are once more striving to place business directly with the domestic consumers at prices which are satisfactory to both parties. The past few months have seen a radical change in general business principles. Contracts on leading chemicals have been placed with consumers through first hands only. This step practically does away with the dealer who, through his unscrupulous speculation, has proved so disastrous to the chemical industry.

SODIUM SALTS

Article	Jan.-March	April	July	Aug.-Oct.
Acetate soda.....	7½@8½c.	9½@12½@11½c.		11½@8½c.
Soda ash, 100 lb....	\$2.25@3.50	\$3.75@3.10		\$3@2.25
Bichromate soda....	18@40c.	45@24c.		22@12c.
Caustic soda, 100 lb.	\$4.50@6.50	\$7@6		\$5.50@4@4.50
Cyanide soda.....	25@30c.	30@40c.		60@40@28c.
Nitrite soda.....	14@50c.	50@17c.		15@8½c.
Prussiate soda.....	22@32c.	32@26c.		25@22c.
Sulphide soda.....	5@6½c.	7@10c.		10@7c.

NAVAL STORES

Turpentine during the week has been very quiet and prices are still falling, with \$1.20 per gal. the prevailing midweek quotation. It is generally assumed that owing to the recent dullness throughout the naval stores list supplies of *rosins* and *turpentine* have been accumulating and that a large surplus now exists in the Southern market. However, the present levels are so close to production cost as to make a curtailment of output necessary and an estimate places the material on hand equivalent to five months' consumption. *Rosins* are nominally in the same position, with offerings of \$12.75 for B-N and \$13@13.25 for W.G.-W.W. grades being turned down by consumers.

MISCELLANEOUS MATERIALS

There is a comparatively firm undertone in the *shellac* market and routine business has not suffered any great depression. Demand has been sufficient to sustain the A.C. garnet grade around 90c. and orange superfine at \$1.05@1.10 per lb. *Blanc fixe* has fallen off under pressure of accumulating supplies and the pulp grade is available at 3@3½c., while the dry grade in considerable quantities can be purchased at 5@5½c. per lb. Buyers continue to pay 14@18c. per lb. for *casein*, depending upon source and quantity, and it is not expected that this price will be lowered.

The Chicago Market

Chicago, Ill., Nov. 11, 1920.

The outstanding feature of the trade is the fact that, while demand continues light and supply plentiful, there are practically no distressed lots in sight, indicating that the speculative element has largely been eradicated. Supplies of all lines are in the hands of producers or legitimate dealers, this indicating that any future price movements will be toward a stable base and not the result of manipulation.

In no line does there seem to be any buying beyond immediate requirements, and the prevailing slowness in all other lines is directly affecting many chemicals. This is particularly true of coal-tar products. The anilines not only are contending with a fall season of unprecedented slowness in the textile industry but are also facing imports from abroad of sufficient volume to affect stocks materially. Low grain quotations and livestock markets are keeping oils at a low level and naval stores, owing to the lack of construction work, have failed to show their customary November strength. Flaxseed receipts continue heavy at primary points, with linseed oil prices correspondingly weak.

HEAVY CHEMICALS

Alcohol leads in interest by reason of sharp reductions in *methyl* grade and in *denatured*, the former being priced now at \$1.90@1.95 per gal. for 95 per cent and the latter at 85c. for 96 per cent. *Ethyl* grade is held firm at \$5.60 per gal. for 190 proof. The reductions mentioned have not brought any noticeable stimulation about. *Formaldehyde* is heard of as offered at prices all the way from 22c. to 28c. per lb., with transactions few and of small volume. *Mercury* is another weak spot, being quoted at \$60 per flask and some being sold at a dollar or two less. A topheavy market points to a further drop.

Reports from the East of heavy receipts of *bleaching powder* have depressed an already weak market and none can be sold above 5½c. per lb. Holders of stock are reluctant to let go at this figure and a negligible amount of business is the result. *Soda ash* is also very weak, spot offers of \$2.05@2.15 per 100 lb. attracting few buyers. *Caustic*

soda is quoted at \$2.25@2.40 for immediate delivery and is in fair demand with the higher figure most closely reflecting present worth. *Soda cyanide*, off in demand and plentiful in supply, is offered at 28c., but 27c. could buy it. *Glycerine*, in spite of curtailed production, continues to encumber the market, with dynamite grade offered at 20c., including drums, and very little sold. It is freely stated that further reduction is looked for.

With the sole exception of *nitric*, acids show weakness in price and poor demand. *Nitric* is being taken up about as fast as offered, prevailing price being about 7c. per lb. for 36 deg. *Acetic acid*, 28 per cent, is nominally 3c. per lb. and 60 deg. *sulphuric* \$16 a ton, with trading so dull that quotations mean very little.

COAL-TAR PRODUCTS

A small amount of business is reported in crudes, principally in benzene, naphtha and toluene. Intermediates are so dull that quotations are purely nominal. *Aniline oil* is quoted at 30c. a lb., *aniline salt* at 38c. and all related products are similarly weak. *Toluene* has witnessed some real demand and has changed hands at 38c. per gal. *Benzene*, at 36c. per gal. is quite firm and *naphtha*, with plentiful supply, is held firm at 35c. The long continued lack of demand in this class of goods seems to point to some additional price reductions before long.

VEGETABLE OILS

A great deal of complaint is heard by consumers of vegetable oils that while their prices of finished products have been materially reduced the public is still being forced by the retailer to pay high prices, thereby keeping consumption at a low figure and accentuating the stagnation of the trade. Trading in this line is inactive, prices being largely nominal. On the local market *linseed oil* is off to 91c. per gal. in sellers' tanks f.o.b. the city and to \$1.17 in single barrels from jobbers' stocks. Even these prices induce but little buying. Reports of frost in Argentina and fluctuating prices on flaxseed in Minneapolis and Duluth have failed to give any color to the market. *Cottonseed oil* continues to drop, planters' "strikes" to the contrary not supporting prices. Most recent offers are for crude in cars at the works, 7½c. per lb., and for prime summer yellow in sellers' tanks Chicago, 9½c. *Crude corn oil* is offered at 9c. in tanks here, and *red oil* is nominally 10½c. in car lots, with no buyers.

NAVAL STORES

Naval stores are as quiet as other lines, but prices remain fairly steady. In barrels, out of stock in small lots, *turpentine* brings \$1.29 per gal. The end of the season is approaching in the South and industrial demand is keeping up, so that the future trend should be either firm or upward. *Kerosin* is quoted at \$13.20 for W.W. and W.C., and only 15c. less for inferior grades. Current fluctuations in foreign exchange cause the export demand of the future to be questionable and this, in turn, is inducing caution on the part of domestic purchasers.

The St. Louis Market

St. Louis, Mo., Nov. 12, 1920.

Compared with the enormous activity of the war years present demand may be considered at a low ebb, but heavy chemical producers do not express themselves pessimistically. They state that the volume of business is satisfactory, considering general business conditions, and that a large part of their production for the coming year is on contract, with many other contracts not yet up for renewal. Shipments on contracts have fallen off very little, but spot business is rather dull. Contract prices remain higher than those of last year, but are below the market prevailing several months ago.

Demand for 66 deg. *sulphuric acid* remains fairly steady, but prices have declined for bulk lots, going down to \$22 per ton from \$24. The price in carboys remains at 1½c. per lb., carload lots. The demand from the oil refineries is becoming stronger and producers believe it will continue that way as long as the reserve oil stocks of the country

continue to decline. The 98 per cent *sulphuric acid* market is quiet, and is quoted at \$25 per ton f.o.b. works. The 60 deg. acid is holding firmly at \$16.50 per ton, or 1½c. per lb. in carboys. *Oleum* is firm at \$28.50 per ton.

Stocks of *muratic acid* are smaller, although demand remains slow. Present price is 1½@2c. per lb. in carboys, against 2@2½c. two weeks ago. In bulk it remains at \$25 per ton.

There is a steady demand for *sodium bisulphate* (niter cake) and on this item prices have advanced. It is quoted now at \$7@8 per ton, as against \$5@6 two weeks ago.

Nitric acid demand is fairly strong and prices are steady. Deliveries are normal. Quotations are \$7 per 100 lb. for the 36 deg. test and \$10 per 100 lb. for the 42 deg. test. Standard mixed acid is held nominally at 1½c. per lb. for the sulphuric content and 1½c. per lb. for unit of nitric, with fairly good inquiry.

Zinc chloride shows activity, the contract price having advanced to \$4.50 per 100 lb., against \$4 two weeks ago. Demand for U. S. Government supplies of *phenol* is quiet with prices at 12c. per lb. in lots of 15 tons or more.

The Iron and Steel Market

Pittsburgh, Nov. 12, 1920.

Production of steel ingots in October was at the rate of about 42,950,000 gross tons per annum, the highest rate shown for any month since December, 1918, with the exception of February and March of this year. The increase over the rate in both September and August, however, was only one-half of 1 per cent. During the month there was a more or less steady decrease in the rate of production, and this decrease has continued, so that the rate today is much below the average of October. Furthermore, production was aligned differently, in October, among producers. Some independent producers curtailed output very materially, while some may have increased their output, and the Steel Corporation, plentifully supplied with orders, certainly did so. The October rate of production is not likely to be equaled until the iron and steel industry has completed its readjustment.

The Steel Corporation's unfilled obligations decreased by 537,952 tons in October, this comparing with decreases of 430,234 tons in September and 313,430 tons in August, while in the fourteen preceding months there had been increases of various amounts.

The October decrease in unfilled obligations was equal to 39 per cent of rated capacity, while shipments may be estimated at about 87 per cent of capacity, which would indicate 48 per cent of capacity for the net bookings, the total bookings minus the cancellations, for even the Steel Corporation, with prices much below those of the independents has had some cancellations. Net bookings at 48 per cent of capacity in October compare with bookings of 53 per cent in September, 57 per cent in August and 85 per cent in July, similarly computed. This decrease in bookings is plainly much less than the decrease in market demand for steel products, and the divergence is readily explained. Ever since the independent prices soared above those of the Steel Corporation the corporation has been offered much more business than it accepted. Of late, in changed circumstances, the corporation has been in position to accept a larger proportion of the business offered, and thus its bookings have not decreased as rapidly as the sum total of market demand has decreased. The independents have been getting the overflow, and the overflow has decreased in correspondingly exaggerated ratio.

STEEL PRICES

In one sense the finished steel market is yielding rather rapidly, for there are price declines when the volume of tonnage that can be secured by cutting prices is quite limited. In another sense it is yielding quite slowly, for when everyone is convinced that independent prices are going to settle at least as far as down to the Steel Corporation level one might expect prices to decline at once and be done with the operation. The explanation, of course, is that steel mills with a considerable volume of contract

business on books are indisposed to cut prices when to do so would be to encourage cancellation of the business they already have.

The Steel Corporation prices are of course unaltered. In the independent market black sheets are down a quarter cent in the week to 6c., galvanized being correspondingly 7.50@7.75c. Bars, shapes and plates remain generally at 3c., with more likelihood of the price being cut for a desirable order. All effort to obtain \$8.50 for tin plate has been abandoned, and odd lots arising in stock are offered at \$7.50.

PIG IRON

A week ago foundry pig iron was quotable nominally at \$45 valley. Quotations have since been made by furnaces at \$40, without any important sales being made, and the market is quotable at \$40. Bessemer remains quotable at \$42 and basic at \$38.50 valley. Declines from the top points reached in August now amount to \$10 in foundry and basic and \$6.50 in bessemer. Part of the declines may be described as practically voluntary reductions on the part of furnaces. Now there is a new attitude. The furnaces see no occasion to make further reductions except when offered suitable inducements by way of actual orders. They point out that the reductions are really large, yet almost no orders have resulted and it is time for consumers to offer inducements. No effort is made to deny that further reductions must come, but there is evidently plenty of time left. Where the market will eventually turn no one ventures to predict. A price of \$28.50 for basic iron would probably be considered quite low in most quarters, but if \$28.50 were to be the eventual turning point, then in declining from \$48.50 to \$38.50 half the total decline has already occurred, and the furnaces consider that quite a concession, particularly for a period of less than two months.

FUTURE OF STEEL PRICES

It is curious that it is commonly if not universally predicted that the independent steel market will decline to the Steel Corporation level, the market then being stabilized, and practically no thought is given to the important point that if the independents are forced to go down to the corporation level it will only be in such circumstances that they will be forced to compete for business, in which case it is a fair presumption that they will cut the Steel Corporation prices. No independent shows a disposition voluntarily to drop to the corporation level. Any decline will be forced by lean order books. Hence while the common prediction is that the independents will get down to the corporation level a more precise prediction would be that the Steel Corporation prices are the only prices at which the independents are unlikely to sell.

In some circles the possibility is now being referred to of the Steel Corporation itself reducing its prices somewhat. The corporation's policy is that of seeking moderate profits only, and the profits have no doubt been eminently satisfactory, particularly in view of the very conservative accounting methods the corporation unquestionably follows. Costs may come down somewhat, although only so recently as Aug. 26 the freight advances effected a large increase in costs. Possibly the corporation may readjust prices on the basis of relative costs, reducing some prices and leaving others alone.

There is a large latent demand on the part of the railroads which are now operated under legislation that seems to insure a fair return, making railroad investment safe if not especially profitable, while there is such control that makes it certain large railroad purchases will not be made unless it is clear the prices are right. If a resumption of buying of steel products is to be led by the railroads the price readjustment may have to be more drastic than would otherwise be the case. It is possible also that there is considerable latent buying by way of investment construction, in cases in which the prospective investors have definite ideas as to the prices they will be charged, and their attitude may have to be taken into account when the steel market finds its eventual turning point in the matter of prices.

Oxalic, crystals.....	lb.	21 - 24	25 - 29
Phosphoric, Ortho, 50 per cent solution.....	lb.	19 - 20	21 - 22
Picric.....	lb.	28 - 35	40 - 50
Pyrogallol, resublimed.....	lb.	2.30 - 2.55	2.60 - 2.65
Sulphuric, 60 deg., tank cars.....	ton	11.00 - 12.00	
Sulphuric, 60 deg., drums.....	ton		
Sulphuric, 66 deg., tank cars.....	ton	18.00 - 19.00	
Sulphuric, 66 deg., drums.....	ton	21.00 - 22.00	22.50 - 23.00
Sulphuric, 66 deg., carboys.....	ton		
Sulphuric, fuming, 20 per cent (oleum) tank cars.....	ton	27.00 - 30.00	37.00 - 42.00
Sulphuric, fuming, 20 per cent (oleum) drums.....	ton	28.00 - 30.00	38.00 - 42.00
Sulphuric, fuming, 20 per cent (oleum) carboys.....	ton	2.00 - 35.00	40.00 - 45.00
Tannic, U. S. P.....	lb.	1.45 - 1.50	1.55 - 1.65
Tannic (tech).....	lb.	.60 - .70	.80 - .90
Tartaric, crystals.....	lb.		49 - 52
Tungstic, per lb. of WO.....	lb.		1.20 - 1.40
Alcohol, Ethyl (nominal).....	gal.	5.75 - 6.25	
Alcohol, Methyl (see methanol).....	gal.		1.12 - 1.15
Alcohol, denatured, 188 proof (nominal).....	gal.		1.05 - 1.10
Alcohol, denatured, 190 proof (nominal).....	gal.		1.05 - 1.10
Alum, ammonia lump.....	lb.	.04 - .04	.05 - .05
Alum, potash lump.....	lb.	.05 - .06	.06 - .07
Alum, chrome lump.....	lb.	.14 - .15	.16 - .17
Aluminum sulphate, commercial.....	lb.	.03 - .03	.04 - .04
Aluminum sulphate, iron free.....	lb.	.04 - .05	.05 - .06
Aqua ammonia, 26 deg., drums (750 lb).....	lb.	.08 - .09	.09 - .10
Ammonia, anhydrous, cylinders (100-150 lb).....	lb.	.33 - .35	.36 - .38
Ammonium carbonate, powder.....	lb.	.14 - .15	.16 - .16
Ammonium chloride, granular (white sulphuric) (nominal).....	lb.	.13 - .13	.14 - .14
Ammonium chloride, granular (gray sulphuric) (nominal).....	lb.	.12 - .13	.13 - .14
Ammonium nitrate.....	lb.	.05 - .10	.11 - .14
Ammonium sulphate (f.o.b. New Orleans).....	lb.	.05 - .05	.06 - .06
Amylacetate.....	gal.		4.50 - 5.00
Amylacetate, tech.....	gal.		4.00 - 4.20
Arsenic, oxide, lumps (white arsenic).....	lb.	.13 - .13	.14 - .14
Arsenic, sulphide, powdered (red arsenic).....	lb.	.18 - .19	.19 - .20
Barium chloride.....	ton	90.00 - 95.00	100.00 - 105.00
Barium dioxide (peroxide).....	lb.	.24 - .25	.26 - .27
Barium nitrate.....	lb.	.12 - .12	.13 - .13
Barium sulphate (precip) (blanc fixe).....	lb.	.04 - .05	.05 - .06
Bleaching powder (see calcium hypochlorite).....	lb.		
Blue vitriol (see copper sulphate).....	lb.		
Borax (see sodium borate).....	lb.		
Bromine (see sulphur, roll).....	lb.		
Bromine.....	lb.	.70 - .80	.85 - .90
Calcium acetate.....	100 lb.	3.50 - 3.55	
Calcium carbide.....	lb.	.05 - .06	.06 - .06
Calcium chloride, fused, lump.....	ton	30.00 - 32.00	33.00 - 35.00
Calcium chloride, granulated.....	lb.	.02 - .02	.03 - .03
Calcium hypochlorite (bleaching powder).....	lb.	.05 - .05	.06 - .06
Calcium peroxide.....	lb.		1.50 - 1.70
Calcium phosphate, monobasic.....	lb.		.75 - .80
Calcium sulphate, pure.....	lb.		.25 - .30
Camphor.....	lb.		1.10 - 1.15
Carbon bisulphide.....	lb.	.08 - .09	.10 - .11
Carbon tetrachloride, drums.....	lb.	.13 - .14	.16 - .17
Carbonyl chloride (phosgene).....	lb.		1.25 - 1.50
Caustic potash (see potassium hydroxide).....	lb.		
Caustic soda (see sodium hydroxide).....	lb.		
Chlorine, gas, liquid-cylinders (100 lb).....	lb.	.09 - .09	.10 - .10
Chloroform.....	lb.	.40 - .43	.44 - .47
Cobalt oxide.....	lb.		3.75 - 4.00
Copperas (see iron sulphate).....	lb.		
Copper carbonate, green precipitate.....	lb.	.27 - .28	.29 - .31
Copper cyanide.....	lb.		.65 - .70
Copper sulphate, crystals.....	lb.	.07 - .08	.08 - .09
Cream of tartar (see potassium bitartrate).....	lb.		
Epsom salt (see magnesium sulphate).....	gal.		1.05 - 1.10
Ethyl Acetate Com. 85%.....	gal.		
Ethyl Acetate pure (acetic ether 98% to 100%).....	gal.		
Formaldehyde, 40 per cent (nominal).....	lb.	25 - 26	27 - 28
Fuel oil, ref.....	gal.		4.25 - 4.50
Fuel oil, crude (nominal).....	gal.		3.25 - 3.50
Glauber's salt (see sodium sulphate).....	lb.		
Glycerine, C. P., drums extra.....	lb.		.77 - .78
Iodine, resublimed.....	lb.	4.30 - 4.35	4.40 - 4.45
Iron oxide, red.....	lb.		15 - 25
Iron sulphate (copperas).....	100 lb.	2.25 - 2.50	2.75 - 3.00
Lead acetate, normal.....	lb.		13 - 16
Lead arsenate (paste).....	lb.	13 - 14	14 - 15
Lead nitrate, crystals.....	lb.		90 - 1.00
Litharge.....	lb.	12 - 12	13 - 13
Lithium carbonate.....	lb.		1.50 - 1.50
Magnesium carbonate, technical.....	lb.	11 - 12	12 - 13
Magnesium sulphate, U. S. P.....	100 lb.	3.00 - 3.25	
Magnesium sulphate, commercial.....	100 lb.		3.50 - 3.60
Methanol, 95%.....	gal.		2.70 - 2.75
Methanol, pure.....	gal.		2.90 - 3.00
Nickel salt, double.....	lb.		.14 - .14
Nickel salt, single.....	lb.		.16 - .16
Phosgene (see carbonyl chloride).....	lb.		
Phosphoric, red.....	lb.	.50 - .55	.60 - .65
Phosphoric, yellow.....	lb.		.35 - .37
Potassium bichromate.....	lb.	.22 - .23	.23 - .24

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar).....lb.	\$0.45 - \$0.47	\$0.48 - \$0.49
Potassium bromide, granular.....lb.	50 - 55	45 - 50
Potassium carbonate, U. S. P.....lb.	171 - 18	181 - 19
Potassium carbonate, crude.....lb.	18 - 181	19 - 20
Potassium chlorate, crystals.....lb.	161 - 161	17 - 171
Potassium hydroxide (caustic potash).....lb.	14 - 16	161 - 17
Potassium iodide.....lb.	63 - 68	70 - 75
Potassium nitrate.....lb.	73 - 75	78 - 80
Potassium prussiate, red.....lb.	36 - 37	371 - 381
Potassium prussiate, yellow.....lb.	240.00 - 255.00	
Potassium sulphate (powdered).....ton		
Rochelle salts (see sodium potas. tartrate).....		
Salammoniac (see ammonium chloride).....		
Salt soda (see sodium carbonate).....		
Salt cake.....ton	52.00 - 55.00	
Silver cyanide (nominal).....os.	1.25 - 1.25	
Silver nitrate (nominal).....os.	60 - 62	
Soda ash, light.....100 lb.	2.15 - 2.25	2.30 - 2.50
Soda ash, dense.....100 lb.	2.50 - 2.75	3.00 - 3.25
Sodium acetate.....lb.	0.81 - 0.9	0.91 - 0.91
Sodium bicarbonate.....100 lb.	2.90 - 3.00	3.25 - 3.50
Sodium bichromate.....lb.	101 - 101	11 - 111
Sodium bisulphate (nitre cake).....ton	7.00 - 7.50	8.00 - 11.00
Sodium bisulphate powdered, U. S. P.....lb.	0.61 - 0.71	0.8 - 0.9
Sodium borate (borax).....lb.	0.91 - 1.0	1.1 - 1.2
Sodium carbonate (soda ash).....100 lb.	2.00 - 2.10	2.15 - 2.25
Sodium chlorate.....lb.	141 - 15	161 - 161
Sodium cyanide, 96-98 per cent.....lb.	28 - 30	31 - 32
Sodium fluoride.....lb.	20 - 201	21 - 22
Sodium hydroxide (caustic soda).....100 lb.	4.10 - 4.30	4.60 - 4.75
Sodium hypsulphite.....lb.		0.4 - 0.41
Sodium molybdate.....lb.	2.50 - 3.00	3.25 - 3.25
Sodium nitrate.....100 lb.	3.00 - 3.00	3.25 - 3.25
Sodium nitrite.....lb.	0.71 - 0.8	0.81 - 0.81
Sodium peroxide, powdered.....lb.	50 - 51	511 - 52
Sodium phosphate, dibasic.....lb.	0.31 - 0.41	0.4 - 0.5
Sodium potassium tartrate (Rochelle salts).....lb.		37 - 38
Sodium prussiate, yellow.....lb.	201 - 21	211 - 21
Sodium silicate, solution (40 deg).....lb.	0.11 - 0.11	0.2 - 0.21
Sodium silicate, solution (60 deg).....lb.	0.21 - 0.3	0.4 - 0.5
Sodium sulphate, crystals (Glauber's salt).....100 lb.	2.15 - 2.50	2.60 - 2.75
Sodium sulphide, crystals, 60-62 per cent (cone).....lb.	0.7 - 0.71	0.71 - 0.8
Sodium sulphite, crystals.....lb.	0.4 - 0.42	0.41 - 0.5
Strontium nitrate, powdered.....lb.	20 - 201	21 - 22
Sulphur chloride red.....lb.	0.8 - 0.9	10 - 101
Sulphur, crude.....ton	16.00 - 20.00	
Sulphur dioxide, liquid, cylinders.....lb.	0.9 - 1.0	1.2 - 1.2
Sulphur (sublimed), flour.....100 lb.		3.70 - 4.35
Sulphur, roll (brimstone).....100 lb.		3.40 - 3.90
Tin chloride, 50 per cent.....lb.	18 - 19	
Tin oxide.....lb.		50 - 51
Zinc carbonate, precipitate.....lb.	16 - 18	19 - 20
Zinc chloride, gran.....lb.	12 - 13	131 - 14
Zinc cyanide.....lb.	45 - 49	50 - 60
Zinc dust.....lb.	12 - 13	13 - 14
Zinc oxide, XX.....lb.	11 - 111	
Zinc sulphate.....lb.	0.31 - 0.31	0.4 - 0.6

Coal-Tar Products

NOTE - The following prices are for original packages in large quantities:

Alpha naphthol, crude.....lb.	\$1.10 - \$1.15
Alpha naphthol, refined.....lb.	1.45 - 1.50
Alpha-naphthylamine.....lb.	48 - 50
Aniline oil, drams extra.....lb.	27 - 30
Aniline salts.....lb.	32 - 33
Anthracene, 80% in drums (100 lb.).....lb.	90 - 1.00
Benzaldehyde (f f e).....lb.	2.00 - 2.10
Benzidine, base.....lb.	1.15 - 1.20
Benzidine sulphate.....lb.	1.10 - 1.15
Benzoic acid, U. S. P.....lb.	80 - 85
Benzoate of soda, U. S. P.....lb.	80 - 90
Benzene, pure, water-white, in drums (100 gal).....gal	31 - 381
Benzene, 90% in drums (100 gal).....gal	35 - 40
Benzyl chloride, 95-97%, refined.....lb.	35 - 40
Benzyl chloride, tech.....lb.	25 - 35
Beta-naphthol benzene (nominal).....lb.	3.50 - 4.00
Beta-naphthol, sublimed (nominal).....lb.	90 - 95
Beta-naphthol, tech (nominal).....lb.	46 - 49
Beta-naphthylamine, sublimed.....lb.	2.25 - 2.40
Cresol, U. S. P., in drums (100 lb.).....lb.	18 - 19
Ortho-cresol, in drums (100 lb.).....lb.	23 - 25
Cresylic acid, 97-99%, straw color, in drums.....gal	1.10 - 1.15
Cresylic acid, 95-97%, dark, in drums.....gal	1.05 - 1.10
Cresylic acid, 50%, first quality, drums.....gal	65 - 75
Dichlorobenzene.....lb.	0.7 - 1.0
Diethylaniline.....lb.	1.45 - 1.50
Dimethylaniline.....lb.	90 - 95
Dinitrobenzene.....lb.	30 - 37
Dinitrochlorobenzene.....lb.	27 - 32
Dinitronaphthalene.....lb.	42 - 45
Dinitrophenol.....lb.	40 - 45
Dinitrotoluene.....lb.	38 - 40
Dip oil, 25%, tar acids, car lots, in drums.....gal	38 - 40
Diphenylamine (nominal).....lb.	60 - 85
H-acid (nominal).....lb.	1.65 - 1.70
Meta-phenylenediamine.....lb.	1.25 - 1.30
Monochlorobenzene.....lb.	18 - 20
Monothylaniline.....lb.	1.75 - 2.25
Naphthalene crushed, in bbls. (250 lb.).....lb.	0.81 - 0.9
Naphthalene, flake.....lb.	0.81 - 0.9
Naphthalene, balls.....lb.	0.9 - 0.91
Naphthionio acid, crude.....lb.	70 - 75
Nitrobenzene.....lb.	12 - 15
Nitro-naphthalene.....lb.	40 - 50
Nitro-toluene.....lb.	18 - 25
Ortho-amidophenol.....lb.	3.20 - 3.75
Ortho-dichlor-benzene.....lb.	15 - 20
Ortho-nitro-phenol.....lb.	75 - 80
Ortho-nitro-toluene.....lb.	25 - 40
Ortho-toluidine.....lb.	32 - 35
Para-amidophenol, base.....lb.	2.50 - 3.00
Para-amidophenol, HCl.....lb.	2.50 - 3.00
Para-dichlorobenzene.....lb.	10 - 15
Paranitroaniline.....lb.	1.15 - 1.20

Para-nitrotoluene.....lb.	1.25 - 1.40
Para-phenylenediamine.....lb.	2.50 - 2.65
Para-toluidine.....lb.	1.85 - 2.00
Phthalic anhydride.....lb.	60 - 70
Phenol, U. S. P., drums (dest.), (240 lb.).....lb.	12 - 14
Pyridine.....gal	2.00 - 3.50
Resorcinol, technical.....lb.	2.90 - 3.00
Resorcinol, pure.....lb.	3.75 - 4.15
Salicylic acid, tech., in bbls. (110 lb.).....lb.	3.75 - 3.8
Salicylic acid, U. S. P.....lb.	40 - 45
Salol.....lb.	85 - 95
Solvent naphtha, water-white, in drums, 100 gal.....gal	30 - 351
Solvent naphtha, crude, heavy, in drums, 100 gal.....gal	19 - 22
Sulphanilic acid, crude.....lb.	32 - 35
Toluidine.....lb.	1.75 - 1.80
Toluidine, mixed.....lb.	45 - 55
Toluene, in tank cars.....gal	35 - 42
Toluene, in drums.....lb.	41 - 42
Xylidines, drums, 100 gal.....lb.	50 - 65
Xylene, pure, in drums.....gal	45 - 47
Xylene, pure, in tank cars.....gal	45 - 45
Xylene, commercial, in drums, 100 gal.....gal	37 - 38
Xylene, commercial, in tank cars.....gal	30 - 30

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark.....lb.	\$0.31 - \$0.33
Beeswax, refined, light.....lb.	34 - 37
Beeswax, white pure.....lb.	55 - 60
Carnauba, No. 1, (nominal).....lb.	80 - 90
Carnauba, No. 2, regular (nominal).....lb.	70 - 80
Carnauba, No. 3, North Country.....lb.	25 - 26
Japan.....lb.	19 - 20
Montan, crude.....lb.	12 - 14
Paraffine waxes, crude match wax (white) 105-110 m.p.....lb.	0.8 - 0.81
Paraffine waxes, crude, scale 124-126 m.p.....lb.	0.8 - 0.81
Paraffine waxes, refined, 118-120 m.p.....lb.	0.9 - 0.91
Paraffine waxes, refined, 125 m.p.....lb.	0.9 - 0.91
Paraffine waxes, refined, 128-130 m.p.....lb.	101 - 11
Paraffine waxes, refined, 133-135 m.p.....lb.	131 - 141
Paraffine waxes, refined, 135-137 m.p.....lb.	141 - 151
Stearic acid, single pressed.....lb.	171 - 171
Stearic acid, double pressed.....lb.	181 - 19
Stearic acid, triple pressed.....lb.	221 - 23

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940.....gal.	\$1.90
Pine oil, pure, dest. dist.....gal	1.50
Pine tar oil, 1st, sp. gr. 1.025-1.035.....gal	48
Pine tar oil, crude, sp. gr. 1.025-1.035 (tank cars) f.o.b. Jacksonville, Fla.....gal	55
Pine tar oil, double ref., sp. gr. 0.965-0.990.....gal	75
Pine tar, ref., thin, sp. gr. 1.080-1.090.....gal	36
Turpentine, crude, sp. gr. 0.900-0.970.....gal	1.25
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990.....gal	35
Pine-wood creosote, ref.....gal.	52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.....280 lb.	\$12.75 -
Rosin E-L.....280 lb.	12.75 -
Rosin K-N.....280 lb.	12.75 -
Rosin W-G-W.....280 lb.	13.00 - 13.25
Wood rosin bbl.....280 lb.	11.00 -
Spirits of turpentine.....gal	1.20 -
Wood turpentine, steam dist.....gal	1.16 -
Wood turpentine, dest. dist.....gal	1.10 -
Pine tar pitch, bbl.....200 lb.	8.50 -
Tar, kiln burned, bbl. (500 lb.).....bbl.	15.00 -
Retort tar, bbl.....500 lb.	15.00 - 15.50
Rosin oil, first run.....gal.	70 -
Rosin oil, second run.....gal.	73 -
Rosin oil, third run.....gal.	90 -

Solvents

73-76 deg., steel bbls. (85 lb.).....gal.	\$0.41
70-72 deg., steel bbls. (85 lb.).....gal.	39
68-70 deg., steel bbls. (85 lb.).....gal.	38
V. M. and P. naphtha, steel bbls. (85 lb.).....gal.	30.

Crude Rubber

Para-Tripriver fine (nominal).....lb.	\$0.22 - \$0.23
Tripriver coarse (nominal).....lb.	15 - 16
Tripriver caucho ball (nominal).....lb.	161 - 171
Plantation—First latex crepe.....lb.	19 -
Ribbed smoked sheets.....lb.	18 -
Brown crepe, thin, clean.....lb.	16 -
Amber crepe No. 1.....lb.	17 -

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.....lb.	\$0.14 - \$0.15
Castor oil, AA, in bbls.....lb.	151 - 161
China wood oil, in bbls. (f.o.b. Pan. coast).....lb.	131 - 14
Coconut oil, Ceylon grade, in bbls.....lb.	14 - 141
Coconut oil, Ceylon grade, in bbls (nominal).....lb.	151 - 161
Corn oil, crude, in bbls.....lb.	11 - 111
Cottonseed oil, crude (f.o.b. mill).....lb.	0.8 - 0.81
Cottonseed oil, summer yellow.....lb.	111 - 121
Cottonseed oil, winter yellow.....lb.	131 - 14
Linseed oil, raw, car lots (domestic).....gal.	1.00 -
Linseed oil, raw, tank cars (domestic).....gal.	93 -
Linseed oil, boiled, car lots (domestic).....gal.	1.01 -

Olive oil, commercial.....	gal.	2.75	—	3.00
Palm, Lagos.....	lb.	.10	—	.10
Palm, Niger.....	lb.	.09	—	.09
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.08	—	.09
Peanut oil, refined, in bbls.....	lb.	.15	—	.15
Rapeseed oil, refined in bbls.....	gal.	1.15	—	1.20
Rapeseed oil, blown, in bbls.....	gal.	1.25	—	1.35
Soya bean oil (Manchurian), in bbls, N. Y.....	lb.	.11	—	.11
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.08	—	.08

FISH

Light pressed Menhaden.....	gal.	\$0.65	—	\$0.70
Yellow bleached Menhaden.....	gal.	.67	—	.70
White bleached Menhaden.....	gal.	.72	—	.75
Blown Menhaden.....	gal.	1.05	—	1.10

Miscellaneous Materials

All f. o. b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.	net ton	\$24.00	—	\$30.00
Barytes, ground, off color, f.o.b. Kings Creek	net ton	22.00	—	26.00
Barytes, crude, 88% (94% ba., Kings Creek)	net ton	10.00	—	12.00
Barytes, floated, f.o.b. St. Louis	net ton	26.50	—	28.00
Barytes, crude, first grade, Missouri	net ton	10.00	—	10.00
Blanc fixe, dry.....	lb.	.05	—	.05
Blanc fixe, pulp.....	net ton	60.00	—	65.00
Cane fixe.....	lb.	.14	—	.18

Financial, Construction and Manufacturers' News

Construction and Operation

Connecticut

NORWALK—The St. George Pulp & Paper Co., 6 Smith St., has awarded the contract for the construction of a 1-story, 65x65-ft. addition to its manufacturing plant on Smith St., to A. R. Malkin Co., 3 Mechanic St. Estimated cost, \$15,000.

District of Columbia

WASHINGTON—The General Purchasing Office of the Panama Canal will receive bids until Nov. 26 for furnishing 6,000 lb. Venetian red, in oil, 300 gal. black locomotive black, grade No. 2, 1,000 lb. Indian red, in oil, 300 lb. green commercial chrome, dry, medium, 10,000 lb. lampblack, in oil, 300 gal. green enamel, 1,000 gal. varnish, danner, white, 3,000 gal. creosote oil, 150 gal. sperm oil, 10,000 gal. linseed oil, 200 gal. muriatic acid, 3,000 lb. lump sulphur, 20,000 lb. lump calcium chloride, 2,000 lb. chloride of lime, 15,000 lb. lye, 100,000 lb. soda ash, 6,000 lb. caustic soda, 3,000 lb. coking.

Idaho

IDAHO FALLS—The Howard Pulp & Paper Co. is having plans prepared for the construction of a news print paper factory including a power plant. Estimated cost, \$4,000,000. T. L. Tomlines, City Bank Bldg., Syracuse, N. Y., engr.

Illinois

CHICAGO—The Alameda Die Castings & Mfg. Co., 314 West Chicago Ave., has awarded the contract for the construction of a 1-story, 150x272-ft. building at 2640 Belmont Ave., to C. B. Johnson & Sons, 111 West Washington St. Estimated cost, \$150,000. Equipment to cost \$200,000 will be installed in same.

CHICAGO—The Purdy Packing Co., 1620 West 21st St., plans to construct a 2-story addition to its present plant.

CHICAGO—Theonett & Co., 2558 Armistage St., plans to build a bottling plant on Helden Ave. between Springfield and Crawford Aves. Estimated cost, \$150,000.

Iowa

FORT DODGE—The Bd. Educ. has awarded the contract for the construction of a 3-story, 190x260-ft. high school to Madsen & Peterson, 616 Builders' Exch., Minneapolis, Minn. A chemical laboratory will be installed in same. Estimated cost, \$645,300. Noted Oct. 13.

SHELLSBURG—The Bd. Educ. will receive bids about Jan. 15 for the construction of a 3-story, 80x110-ft. grade high school. A chemical laboratory will be installed in same. Estimated cost, \$100,000. A. K. Rife, secy. J. G. Ralston, 709 L & J. Bldg., Waterloo, archit.

Kansas

CANEY—The city is having plans prepared for the construction of a filtration plant. Black & Veatch, Mutual Bldg., Kansas City, Mo., engr.

Maryland

BALTIMORE—The City Council has awarded the contract for the construction of a 3-story, 76x271x50x241-ft. school at 76 Latrobe Park to the Standard Constr. Co., 1713 Sansome St., Philadelphia, Pa. Estimated cost, \$195,000.

Massachusetts

SOMERSET—The Somerset Stove Fdry. Co. has awarded the contract for the construction of a 1-story, 70x160-ft. foundry to Beattie & Cornell, 33 North Quarry St., Fall River. Estimated cost, \$50,000. Noted Oct. 6.

SOUTH HADLEY—Mt. Holyoke College plans to build a science building. Estimated cost, \$500,000. M. E. Woolley, pres.

Michigan

RIVER ROUGE—The Bd. Educ. will soon award the contract for the construction of a 3-story high school on Dearborn Rd. A chemical laboratory will be installed in same. Estimated cost, \$750,000. A. R. Heuer, pres. Van Leyen, Schilling, Keough & Reynolds, 356 Cass Ave., Detroit, archts.

Minnesota

ATKIN—The Bd. Educ. is having plans prepared for the construction of a 2-story, 102x125-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$175,000. Henry S. Swanson, Crosby, archit. and engr.

New Jersey

ATLANTIC CITY—The Bd. Educ. Atlantic and Pacific Aves., plans to build a 3-story high school. A chemical laboratory will be installed in same. Estimated cost, \$1,000,000.

RIDGEFIELD—The Continental Folding Paper Box Co., 122 Washington St., Brooklyn, N. Y., will soon award the contract for the construction of a 2-story, 100x500-ft. factory on Grand Ave. and Hall St. W. B. Wills, Inc., 1181 Myrtle Ave., Brooklyn, N. Y., archit. and engr.

New York

POUGHKEEPSIE—The State Hospital Comm., Capitol, Albany, will receive bids until Dec. 1 for the construction of additions and alterations to the water supply system, including additional filters, etc., at the Hudson River State Hospital here.

Ohio

IRONTON—The Ironton Firebrick Co., Hayward Bldg., plans to build an addition of two 30-ft. round downdraft kilns.

MARION—The city is having plans prepared for the construction of a sanitary sewer system and sewage disposal plant. Estimated cost, \$1,000,000.

YOUNGSTOWN—The city is in the market for laboratory equipment, etc., at the Municipal Contagious Hospital. Estimated cost, \$60,300.

Pennsylvania

GREAT BEND—The N. H. Parke Leather Co. is having plans prepared for the construction of a 3-story, 75x200-ft. tannery. Estimated cost, \$150,000. Lockwood, Green & Co., 101 Park Ave., New York City, archts and engr.

PHILADELPHIA—The Belmont Packing & Rubber Co., 133 North 2nd St., has awarded the contract for the construction of a 2-story, 130x190-ft. addition to its plant on Coral and Wheatstear Sts., to G. Kessler Constr. Co., Drexel Bldg., Philadelphia, Pa. Estimated cost, \$60,000.

Texas

DALLAS—The Baptist Memorial Sanitarium, Junius and College Sts., is having plans prepared for the construction of a 5-story, 100x120-ft. hospital. Chemical laboratories will be installed in same. Estimated cost, \$800,000. C. D. Hill & Co., S. W. Life Bldg., archit.

DALLAS—The City and Dallas Co. are having plans prepared by H. M. Greene, archit., North Texas Bldg., for the construction of a hospital to cost about \$450,000. The city voted \$225,000 bonds, county will vote equal amount. Chemical laboratory equipment, including X-ray, etc., will be installed in same. F. W. Wozencraft, mayor.

LUBBOCK—The West Texas Sanitarium Association is having plans prepared for the construction of a 4-story sanitarium. A chemical laboratory will be installed in same. Estimated cost, \$110,000. Henry T. Phelps, Gunter Bldg., San Antonio, archit.

RANGER—The Ranger Boiler Wks. plans to build a sheet steel and sheet iron manufacturing plant. Estimated cost, \$100,000. L. C. McFall, pres.

Wisconsin

CLEAR LAKE—The Bd. Educ. will receive bids about Dec. 15 for the construc-

tion of a 2-story consolidated school. A chemical laboratory will be installed in same. Estimated cost, \$75,000. E. Enderbohn, clk.

MERRILL—The Secretary of the Bd. Educ. will receive bids about Dec. 15 for the construction of a 2-story, 140x178-ft. grade school and a 75x120-ft. addition to the high school. A chemical laboratory will be installed in same. Estimated cost, \$260,000. Parkinson & Dockendorf, Linker Bldg., Lacrosse, archts. and engr. Noted Oct. 6.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1920 meeting Dec. 27, 1920, to Jan. 1, 1921, at Chicago, Ill.

AMERICAN CERAMIC SOCIETY will hold its annual meeting the week of Feb. 21, 1921, at Columbus, Ohio, with headquarters at the Deschler Hotel.

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29, 1921.

AMERICAN GAS ASSOCIATION is holding its second annual convention at the Hotel Pennsylvania, New York, Nov. 15 to 20.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its winter meeting at New Orleans, Dec. 6 to 9. Headquarters will be at the Hotel St. Charles.

AMERICAN MINING CONGRESS is holding its convention in Denver Nov. 15 to 19.

AMERICAN PETROLEUM INSTITUTE will hold its annual meeting on Nov. 17, 18 and 19, in Washington, D. C. Headquarters will be at the New Willard Hotel.

AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS' 1920 ANNUAL MEETING will be held in the Engineering Societies' Building from Dec. 7 to 10 inclusive.

AUTOMOTIVE EQUIPMENT ASSOCIATION is holding its second annual exposition in the Coliseum, Chicago, Ill., this week. Trucks, automobiles, tractors, motor buses and equipment for airplanes and submarines will be displayed. Meetings are at the Congress Hotel.

COMMON BRICK MANUFACTURERS' ASSOCIATION OF AMERICA will hold its annual meeting at the Hotel Pennsylvania, New York City, Jan. 31 to Feb. 4.

FEDERATED AMERICAN ENGINEERING SOCIETIES will hold its first meeting in Washington, D. C., Nov. 18 and 19. American Engineering Council will hold its organization meeting Nov. 20. Headquarters for both will be at the New Willard Hotel.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at the Statler Restaurant, Newark, N. J., the second Monday of every month.

PHILADELPHIA SECTION, AMERICAN CHEMICAL SOCIETY, will hold its regular meeting Nov. 18 at the Engineers' Club, Philadelphia. Ellwood Hendrick will speak on "Relativity and Life."

TAYLOR SOCIETY will hold its annual meeting Dec. 2, 3 and 4 in the Engineering Societies Bldg., New York City.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: Nov. 19, American Chemical Society; Dec. 10, American Chemical Society, joint meeting with Society of Chemical Industry, American Electrochemical Society and Société de Chimie Industrielle; Jan. 7, American Chemical Society; Jan. 14, Society of Chemical Industry, Perkin Medal award; Feb. 11, American Electrochemical Society, joint meeting with Society of Chemical Industry, American Chemical Society and Société de Chimie Industrielle; March 11, American Chemical Society, Nichols Medal award; March 25, Society of Chemical Industry; April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

New Import and Export Classification Needed

WITH the expansion of the chemical industries, it has become necessary to rely more and more for commercial information upon the statistics of imports and exports compiled by the Bureau of Foreign and Domestic Commerce. There is urgent need for a new classification of these figures, as well as for the consolidation of the Bureau of Customs Statistics of the Treasury Department and the Bureau of Foreign and Domestic Commerce of the Department of Commerce. A plan to put these reforms in effect has been agreed upon by all concerned, but unless Congress can be induced to provide the necessary funds before Jan. 1, it will be necessary for the improvement to be delayed for another year.

As a result of studies begun some time ago, new classifications have been arranged. The new import classification covers 984 separate commodities, as compared with 700 in the present schedule. The export classification likewise has been increased from 700 items to 1,234. It was expected that these new schedules would be put into effect Jan. 1, 1921, but the additional work demanded of the Statistical Division of the Bureau of Foreign and Domestic Commerce, owing to the tremendous growth of chemical imports and exports since the war, makes it impossible to start work under the new classification unless Congress provides additional funds for statistical work.

At its last session Congress was asked by the Secretary of Commerce for \$400,000 for compiling foreign trade statistics, but no appropriation was made. It was proposed at the same time to transfer the control and expense of operation of the Bureau of Customs Statistics in the New York Custom House from the Treasury Department to the Department of Commerce and perhaps consolidate it with the Division of Statistics of the Bureau of Foreign and Domestic Commerce. The estimate of \$400,000 is approximately double the present cost of these two statistical bureaus which it is proposed to unite, but the additional amount was expected to take care of extension of import and export classifications; introduce more efficient methods for compiling and publishing monthly and annual reports; compile statistics of exports by states of origin; furnish special statistical statements to interested parties in more detailed form than is customary in the monthly summary; and otherwise improve the statistical service for the benefit of the Government, trade and commercial organizations and firms engaged in foreign trade. The advantages of this consolidation and improved service will be quite obvious to those who now have to deal with the separate bureaus.

It is now planned to request the Appropriations

Committee of Congress to hold a special hearing on this estimate in advance of the hearings on the annual appropriations for the fiscal year commencing with July, 1921, for the purpose of explaining the necessity for additional appropriations for statistical work in order that the revised import and export schedules may be put into effect Jan. 1, 1921. According to law the annual report on statistics of commerce and navigation of the United States with foreign countries is published with the close of a calendar year, thus making it necessary to initiate changes in the classification at the beginning of a calendar year. It is to be hoped that a post-war measure of such importance will receive sympathetic treatment at the short session of Congress, and we suggest that representatives of the industries concerned exert all legitimate influence to bring this about.

Production Costs And Commodity Prices

NO DOUBT a great many persons would disagree with a statement that in the orgy of high commodity prices from which the country has now begun to emerge prices were dictated by costs, and yet as to many industries there is ground for maintaining such a position. Of course the qualification must be made that very large profits were added to the costs before the selling prices were named, but that is another story. The manufacturer saw that it was a "sellers' market" and in endeavoring to produce at the maximum rate possible he had no incentive to hold down his costs, for any extra cost could be added to the selling price, with a liberal toll in profits.

The new idea in manufacturing is that selling prices are going to dictate costs. The seller is not going to make prices in future, as there is to be a "buyers' market." The buyer knows very little about costs, but is good at making comparisons between prices of the various things he buys. He may not be able to tell from its looks whether a factory makes overcoats or shoes, but if he finds that overcoats have come down to a certain relation with the pre-war price he expects shoes to do the same, or *vice versa*, according to which is the lower. When copper is selling at less than its 1913 price and less than its ten-year pre-war average he is suspicious of pig iron when it does not do the same thing. If the pig iron producer cites his costs the buyer, having now an opportunity to speak, is likely to say, "So much the worse for your costs." Then the merchant-furnaceman is likely to have a conference with the coke producer and the iron ore producer.

The great explosion has been the explosion of the theory that the dollar is worth only fifty or forty cents, or perhaps the proverbial thirty cents. One can spend

his dollars for copper, or pig iron, for wheat, or cotton, or movie shows, or various other things. The tables are turned. The profiteers talked about forty-cent dollars. Now the buyer has an opportunity to talk and he will inquire why his dollar will not buy as much of one thing as of another.

Time is a great corrective, and time is going to aid the buyer in coming into his own. If the producer has costs that are too high he will be given time to correct the situation. If the workman is still spending money and does not want to work hard he will be given time to spend the money and reform his mind.

In the readjustment of costs two distinct elements that make up costs are to be recognized. One of the elements is the efficiency of the manufacturing organization that produces, while the other is the profit of some one from whom raw materials or supplies are purchased. The first item is being shaken out. Machinery is as efficient as formerly, while some workmen are not. They do not produce as much per day as formerly. Every day of late one has heard of cases of a factory closing for one day or two days a week and finding its output increased instead of diminished, or of cases of 10 or 15 per cent of the workmen being "laid off," with the remainder producing more than the full quota had previously produced.

There are few manufacturing industries that do not buy large quantities of supplies. Those supplies have been high priced and have increased the cost. When inordinate profits are eliminated the costs of the manufacturer or assembler will be reduced. If the reduction does not occur voluntarily time will be given for reflection. While in the past increases have been handed up the line to the final selling price to the ultimate consumer, reductions will now pass down the line. The country will not be really active industrially until it engages in the construction work that is so much needed, the work for which the investor pays, and the investor will have definite ideas of what a construction job should cost him.

Western Industrial Growth

And Its Influence on Chemical Development

ECONOMICALLY the increase in population of the Western states is of more than local interest. The rapid growth of a few rather limited areas has resulted from agricultural or from industrial developments that have gained impetus during the last decade. Arizona and Montana, through irrigation, have become agricultural, no longer to be considered as mining states only. California south of Tehachapi is becoming an industrial region. Even in the San Joaquin and Sacramento valleys, which have become one almost continuous garden, there is considerable manufacturing in the larger cities. The San Francisco Bay district, at the gateway of an important avenue of trade, no longer handles only the articles of commerce passing through the port, but is supplying manufactured products of its own for export and for shipment to other sections of the country; in 1919 the value of manufactures was over \$750,000,000. More than two hundred new industries have been established during the first nine months of this year in the San Francisco district, and this number has been exceeded in the territory contiguous to Los Angeles. The Columbia River basin is developing along manufacturing lines and, together with British Columbia has established a paper and pulp industry which

should become of more than local importance. While the Puget Sound country and the Northwest as a whole is principally a lumber-producing region, the output of manufactured products is increasing. So the mountain states are emerging from the mining and grazing into the agricultural, and the Pacific Coast states from the agricultural and lumbering into the industrial stage of economic development.

The chemical industry is not a pioneer; it follows rather than leads and grows best where general manufacturing has become well established. Along the Pacific Coast where raw materials are available the chemical industries have a fertile field for growth, not only to meet local needs but also to supply the rapidly developing Oriental market for chemical products.

Good Rails Are More Than Sulphur Prints

TO WHAT end are all Dr. BURGESS' tests? "Why, to separate good rails from bad ones," is the ready rejoinder. But do they? These tests, probably the most minute study ever made of a rail rolling, performed in painstaking detail, picture rails of all sorts, like men from all over the globe—black, yellow, high cheek-boned, dolichocephalic. And they're all good! Witness the report from the railroad company: "There have been no failures of Hadfield rails or of the Maryland Specials."

A metallographist, if asked to state the fundamental axiom of his science, might respond that metallographical uniformity is synonymous with metallurgical excellence. But he would be placing the cart before the horse, for it is not always true even that metallurgical excellence demands microscopic homogeneity; furthermore excellence certainly does not stop with uniformity, nor is metallurgy limited by the microscope. Following analogous sophisms, are not metallographists, chemists and testing engineers in danger of building up a picture of what good metal ought to look like, analyze like, and test like; and then when they find a piece of metal which approximates this masterpiece, say, "Behold, here is a really excellent rail"?

Perhaps Dr. BURGESS has fallen into this trap when he says, "Recalling the greater uniformity of the sink-head over the comparison ingots as shown in nearly all other mechanical tests, in less segregation, greater homogeneity as shown by sulphur prints and etching, less amount and variability in discard to sound steel, the question of the significance and interpretation of the drop test may, it would seem, be raised with propriety," and then cites as evidence against the drop test the fact that it failed to show differences among the three Maryland heats. It was unmistakably able, however, to distinguish between the Hadfield ingots and the Maryland ingots, and the latter stood punishment better, something apparently which was not expected.

What does Service, the court of last resort, say? Its only remark as to relative quality is: "The average abrasion of the No. 1 Hadfield rails was 0.42 sq.in., that of the Maryland Special rails 0.37. Abrasion for No. 2 rails was 16.1 per cent for Hadfield and 9.7 per cent for Maryland Special."

CHEMICAL & METALLURGICAL ENGINEERING has been glad to devote all necessary space to present the record of the work described by Dr. BURGESS. It is instructive in many obvious ways, possibly not least of which is the reflections it ought to excite in the mind of a philosophical metallurgist—if there is such a person.

Trade Wastes and Stream Pollution

ATTENTION is directed by WILLIAM H. WELLS, of the New York State Conservation Commission, in a recent number of *Science*, to the need of more intensive study of the pollution of streams from trade wastes. When we consider the millions spent in carrying water to cities, in protecting watersheds, in filtering, etc., we observe how needful is uncontaminated water. A stream is, in a way, a living thing in which a great biological equilibrium is and must be maintained. As soon as this is disturbed we meet dangers to health and disturbance in the cycle of life. Sometimes one small industry is enough to bring this about, and unless precautions are taken the wastes of many industries are almost certain to do it. If the oxygen dissolved in water becomes diminished, the fish will suffocate, for water is to fish what both earth and air are to land animals. Organic wastes have the power to absorb oxygen from the water, and thus make it uninhabitable for fish life. It is rare indeed that fish are no more found in streams because of overfishing. They swim away to other waters because they cannot get enough air, or because they meet some trade waste that makes life unbearable to them.

The amount of contaminating material a water can absorb without injury to its various uses is strictly limited by the rate at which such substances may undergo physical or chemical change. This, in turn, depends upon the biological capacity of the stream to bring about this change.

Every trade waste needs special study, and splendid work has been done in individual instances. Generally speaking, however, we let by far too much pollution into our streams, using them merely as vehicles of transportation to carry offensive matter from our neighborhood to another whence fish have long since departed. There is room for much improvement in this connection. So far as pollution by sewage is concerned we believe that as soon as some practical method of drying sewage is discovered we shall see all of the sludge turned to inoffensive nitrogen fertilizer, while the chlorinated effluent will harm neither man nor beast.

Only Applied Research Produces Profit

A SOUND theory is always valuable, a correct result of careful research is always an asset; but until translated into useful and used form neither produces any dividends. In no field is this more certain than in chemical industry.

In his recent address, "Thrift in Coal," delivered before the Iron and Steel Institute on Oct. 22, GEORGE OTIS SMITH stressed this point very effectively. He was speaking of boiler-firing results in a large plant which prided itself on the high-grade fuel burned, about 15,000 B.t.u. per pound. This plant was getting only the equivalent of about 11,000 B.t.u. because of poor operating practice, and it is with full justification that Dr. SMITH said of the manager: "That coal user needed expert firemen more than chemists—better practice rather than more theory."

Such a situation might seem at first thought to be an indictment of the chemist. In some cases the defect is chargeable to the research man or the chief of the laboratory, but more frequently it is probably the manager or superintendent who is at fault. Any competent chemist, whether engaged only for the control laboratory work or for original research, is a potential

asset. However, his value as an operating asset is only potential until the manager gives him an opportunity, indeed, encouragement, for direct application of laboratory results in the plant.

Teamwork in the relationship between chemist and superintendent or chemist and manager is a first essential. Each has an important element to contribute in the application of the laboratory results. The laboratory data are cold figures without the interpretation of the chemist. But an impossible situation and impractical results may often result if the interpretation is solely upon the basis of laboratory ideas. A sympathetic understanding of the limitations of the laboratory as well as cordial appreciation of its possibilities will do much to vitalize the product of the workers with beaker and test-tube. On the other hand an intelligent study of the practical plant problems by the chemist, combined with tact and patience in seeking to apply laboratory results, is also an essential prerequisite to success.

Knowing Something About The Other Fellow's Business

DURING the discussion of a paper before the American Zinc Institute in Chicago recently someone stated that one of the reasons for the high recovery of zinc in European smelting practice was the fact that the clays used in making the retorts were of better quality abroad. If the Institute had been informed in the work of the American Ceramic Society this erroneous observation would have been immediately challenged, for the fact is that the United States produces clay of every sort equal to or better than the European product; and that several grades of German clay held at a premium previous to the war now sell at a discount on the American market. The metallurgist must work with the ceramist to find the solution of the problem of iron, lime and silica content in zinc slags, and the consequent reactions on retorts; to know that a refractory composition is often made less refractory by the addition of a more refractory material to the mix, as shown in eutectic diagrams. In turn the ceramist must be advised as to the composition of various ores and slags in order to select the better clays for refractories. Only by a constant interchange of ideas during the rapid progress of both industries can the best results obtain.

It is equally necessary that the chemical engineer be informed as to the efforts of the mechanical engineer in improvement of machine design. Glaring examples of lack of such knowledge exist in many chemical plants today, with absurd designs worked out by chemists where standard machinery might have been applied. Likewise the chemical engineer must also know the better structural methods developed by the civil engineer, or much waste results.

And so on in every line of engineering practice. Instances might be multiplied, all leading to the conclusion that progress will be most effective when we have the closest co-operation among related interests. Just how this can best be accomplished is problematical. Much depends upon the general intelligence and breadth of vision of the individual—upon a natural realization of the incompleteness of his own profession and its probable dependence in some detail or other on a related subject. The next best thing to knowing a subject first-hand is to know where to look for the information. Usually it is to be found close at hand, though sometimes in unexpected places.

Readers' Views and Comments

The Chemist and the Coking Industry

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read with much pleasure the article by R. S. McBride on "The Chemical Profession, Its Opportunities and Responsibilities," which appeared in *CHEMICAL & METALLURGICAL ENGINEERING* of Sept. 8.

In this article I note the following paragraph:

We have whole industries neglected by the chemist. Coking, except in a very few cases, is undirected by science. It remains a mechanical-engineering art, almost, in fact, a trade, so largely is it guided by rule-of-thumb methods.

I presume that in writing the above the author had especially in mind the beehive coking industry, regarding which the statement is entirely correct. I think we can say, however, that the coking industry in America is today the byproduct coking industry. It is some years since the production of byproduct coke exceeded that of the beehive oven and the problems that are before the producers and users of coke are essentially confined to the byproduct oven. The United States Geological Survey stated in its last annual report on this subject that the capacity of the byproduct coking plants of the country is now approximately 80 per cent of the total requirements of the metallurgical coke users.

If we accept this statement, I believe there is no doubt that there are only a very few industries in America in which the chemist plays a more important part. The two systems of byproduct coking which are prominent in this country are represented by the Koppers Company of Pittsburgh and ourselves. The Mellon Institute of Pittsburgh is very largely given over to research work. This was founded by the financial interests which control the Koppers Company and it is working very closely with that company in the solution of chemical problems which constantly come up in the development of the byproduct coking industry. Our own company has an organization of considerably over one hundred chemists, outside of those doing routine work, and the time of these men is largely taken up in the study of problems connected with the development of the coking process and the use of the products obtained therefrom. Practically every proposed modification of an old method and every problem connected with a new method, or with a different or more complete utilization of products, is submitted to be worked out by these research men, and every process connected with the industry, from the routine analyses of the coals used clear through to the finished products ready for shipment, is constantly checked by our chemists.

Not only is this the case in the operations of the two companies named, but every independent operator of byproduct ovens has its organization of chemists, and the United States Steel Corporation, which operates a considerable number of plants, has an important central laboratory in which the men are constantly engaged in research work, looking to the betterment of the operation in addition to the routine checking of every part of the process which, as far as I know, is

carried out at every byproduct coking plant in the country.

I know you will be glad to have these facts and I believe the byproduct coking industry is one of the best examples of the importance of the chemist in the development of modern industry.

Somet-Solvay Co.,

W. H. BLAUVELT.

Synthetic Production of Hydrocarbon Fuels

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read with great interest Mr. Acheson's letter in your issue of Aug. 18, and comment thereon by Mr. Birdsall on page 606 of the Sept. 29 issue.

The question raised by these gentlemen is one which will well merit attention. Mr. Birdsall's suggestion as to the production of a pure hydrocarbon i.e., pentane—in place of the natural mixed products is a likely result. In other words, when man produces a hydrocarbon he will probably excel nature, just as he generally excels her when he duplicates any natural product by controlled processes.

The gentlemen mentioned may be interested to know that I have developed a successful method of effecting an aqueous solution of carbon from cheap materials such as coke, etc., but have not as yet succeeded in producing synthetic products of commercial use.

Cleveland, Ohio.

ARTHUR R. BULLOCK.

A Note on Research

To the Editor of Chemical & Metallurgical Engineering

SIR:—Permit me to second most heartily the thought expressed in the editorial entitled "A Note on Research," published in your Oct. 13, 1920, issue. There is very grave danger that the periodical effort to "organize" and "systematize" research, which is just now in full swing, may defeat its own end. It is no more possible to place real research on a business basis than to organize the writing of poetry and music. Who, for instance, would look for a *real* contribution to dermatology from the chemist to a state geological survey, and yet this has recently happened.

University of Alabama,
Dept. of Chemistry and Chemical Engineering.

STEWART J. LLOYD.

German Exporter Asks Cash Against Documents

A prominent German house exporting chemicals, drugs and related articles has published in Argentina the following statement of its terms of sale:

In regard to our conditions of sale, we must demand payment against delivery of documents by reason of the present economic conditions. The unfavorable state of German exchange carries with it a great risk since we sell in Swiss francs. Should our exchange improve, we will experience a loss which may be very considerable between the date of the invoice and receipt of payment against documents.

By giving credit to our clients this risk would be too great and we would be obliged to invoice in German marks, leaving to our customers all the risk of the exchange, a thing which is not to their interest. The payment of our invoices made out in Swiss francs may be made, according to the desire of the client, also in marks or American dollars at the exchange of the day.

Chemistry and the Food Industry

An Outline of the Far-Reaching Importance of Applying the Principles and the Technique of Biochemistry to the Solution of Problems Relating to the Industries That Use Agricultural Raw Materials

By CARL L. ALSBERG*

THE food industry is the basic industry and the largest industry of every country. It is the key of all key industries. The value of its products far exceeds that of any other industry or of any group of them. In 1914 the foods manufactured in the United States were valued at \$4,816,709,000—and this figure does not include foods which were sold for consumption without going through some form of manufacturing process. In that year iron and steel products had a value of \$3,223,144,000. The largest single food industry in point of value of the finished product is that of the slaughter house, the products of which in 1914 were estimated to be worth \$1,651,965,000. Improvements and economies affecting the production, preparation, distribution and preservation of food hold a place of vital importance to the people far above that occupied by any other industry.

LIMITED APPLICATION OF SCIENTIFIC RESEARCH TO FOOD INDUSTRIES

Despite the tremendous importance of the food industry, the application of the results of scientific research to it hitherto have been limited. Such efforts have been toward improving the methods of producing raw materials—that is to say, to increasing either the yield of crops per acre or reducing the labor required for the production of each food unit. Until recently, with a few exceptions such as sugar refining, milling and brewing, but little application of chemistry or chemical engineering has been made to the manufacturing of the raw material produced in agriculture into the finished product suitable for use upon the table.

The reason for this is very simple. The manufacturing of the raw materials into products fit for food was conducted practically entirely in the home. Just as carding, spinning and weaving were transferred from the home to the factory more than a century ago, so during the past few decades there has been a similar gradual transfer from the home to the factory of many of the processes of manufacturing finished food out of the raw materials. This translocation is only in its beginning. Ultimately it will have a more profound effect upon civilization than the development of the textile industries, for it will open the gates of an immense reservoir of labor, the labor of women, who comprise half the population. Whether or not the prospect is a pleasant one is another matter. Even today the demand for canned goods is a good index of unemployment. The urban laborer's wife seeks to lighten her burden, when the family is prosperous, and the first method that suggests itself is the purchase of ready-to-serve foods.

In this transfer the methods of the home were the first to be used in the factory. Usually these methods, satisfactory enough for small-scale operations, are

wasteful and impracticable on a large scale. A process that may be sanitary and cleanly in the kitchen often becomes filthy and dangerous in the factory.

CHEMICAL CONTROL IN FOOD MANUFACTURING AS A RESULT OF THE FEDERAL AND STATE PURE FOOD LAWS

Until very recently, but few factories had introduced chemical methods of control. The introduction of these methods has been hastened by the necessity of controlling products to meet the requirements of Federal and state pure food laws. It is not the least of the services rendered by such legislation that it has opened the eyes of many a manufacturer to what trained men can accomplish in improving processes, reducing waste and eliminating uncertain rule-of-thumb methods. Today, in most of these plants, chemists would be retained if all food legislation were wiped off the statute books.

Food manufacturing, since it is so new as an industry, presents to the chemist a multitude of problems, many of them of the most profound economic importance.

CHEMICAL PROBLEMS TO BE SOLVED IN THE MILLING INDUSTRY

In the milling industry, which was among the first to introduce exact factory control, there remain problems well worthy of any chemical engineer's attention; problems, the solution of which would influence human affairs as profoundly as any discovery in metallurgy. Thus wheat must be moistened—"tempering," the miller calls it—before milling. How much it is moistened depends upon the head miller's judgment. He must base his judgment not merely upon the characteristics of each lot of wheat to be milled but also upon the weather. It is self-evident that on a humid day fewer fine particles pass through a given sieve than on a dry day. If the wheat is too moist or not moist enough, or there is a change of weather which checks the dessication of the stock as it passes through the mill, particles of flour may pass over sieves that should pass through them. Thus perfectly good flour may pass into the feed-bin instead of into the flour sack. It is one of the head miller's duties, by constantly readjusting the equipment, to see that this does not occur. In doing this he relies chiefly on his judgment. There can be no doubt that if the tempering of wheat were to be done in all mills on some still-to-be-determined scientific basis; and if the operation of milling were to be conducted under controlled conditions of temperature and humidity, say in an inclosed system, the amount of perfectly good flour that could be saved for human consumption would be tremendous.

Though wheat is not a particularly good food, it is supplanting other bread grains all over the world. This is partly because it is, in a sense, a time-saving crop, and partly because it contains gluten. An hour's labor

*Chief, Bureau of Chemistry, U. S. Department of Agriculture.

will produce more food energy in the form of wheat than in almost any other form. By virtue of the properties of its gluten, wheat flour when mixed with water yields a tenacious elastic mass, dough. The carbonic acid gas generated by the yeast used to leaven the dough cannot therefore escape into the atmosphere as it does from a mixture of corn flour and water. The gas bubbles are held enmeshed in the gluten in such manner that when the gluten is set by coagulation in the oven, the bread has a peculiarly desirable flavor and texture. The property of gluten to yield a tough elastic dough makes it possible to bake leavened bread. This property it owes to its physical state, and not, so far as present knowledge goes, to the chemical structure of the molecule of the proteins of which it is composed. There is, as far as it is possible to foresee at the present time, no theoretical reason why other proteins in other bread grains are not susceptible of such manipulation as to give to them the physical properties of gluten. It is a problem of colloid chemistry. To discover the method by which this can be brought about will make it possible to produce a loaf of leavened bread from other materials than wheat. The economic significance of such a discovery is so obvious that it does not require elucidation.

This is not the only problem of the cereal industries. Baking is still largely an art and not a science. Even the grading and standardizing of its basic raw material, flour, is in its infancy. Years of research will have to ensue before it will be possible to standardize fully the processes of baking and to control such factors as the reaction and moisture content of the dough and the conditions of yeast growth. Even the factors that control the "going stale" of bread are not understood. It certainly is not a mere drying out. In some localities at times as much as 7 per cent of the commercially baked bread has gone stale before it was sold.

ECONOMIC IMPORTANCE OF THE UTILIZATION OF GRAIN SORGHUMS

One of the biggest problems of the cereal industries of the United States is the utilization of the grain sorghums, such as kafir, feterita, proso, milo maize and their relatives. The amount of land that can be kept under cultivation in the semi-arid portion of the United States, which includes much of western South Dakota, Nebraska, Kansas, Texas and much of the Southwest generally, depends to no inconsiderable degree upon the price of grain sorghum. Anything that will widen the market for this crop will inevitably make agriculture in this section more profitable and will extend the area of this very large portion of the United States that can be subjected to cultivation.

Grain sorghum has about the composition of corn. Before the war it was sold at a considerable discount under corn because practically the only outlet for it was in competition with corn as stock feed. Under normal conditions the price should be something like 15 per cent under that of corn, since it has a corresponding lower feeding value. There is, therefore, a demand for a commercial outlet for grain sorghum and it is already beginning to be used for alcohol production.

It should be possible to find a future outlet in the creation of a kafir corn products industry producing essentially the same materials as the corn products industry—i.e., starch, glucose, dextrine, oil and byproduct feeds. In addition, there are indications that wax may also be obtained. The man who creates this or a similar industry using grain sorghum as raw material

will as surely confer a tremendous blessing upon the semi-arid regions of the United States as he who builds an irrigation system. This man must be a chemist or a chemical engineer.

OTHER CHEMICAL PROBLEMS IN THE DAIRY INDUSTRY

There are many other problems in the dairy industry demanding study. The production of butter and the control of its composition and texture involve problems in the chemistry of emulsions worthy of any physical chemist's attention. Indeed, it is by no means inconceivable that there is some more efficient way for cutting the emulsion which we call milk than by the ancient mechanical process of churning. The production of butter substitutes, a rapidly growing industry, presents quite analogous problems. To give to these substitutes all the nutritive qualities of butter is a problem quite capable of solution. It awaits the attention of some biochemist.

CHEMICAL PROBLEMS IN CATTLE FEEDS

Dairying is not the only part of animal production that is in process of being made over by the chemist. He is bringing about a revolution in the use of feeding stuffs for beef, pork and milk production. Corn, for example, is not a very efficient feed, and biochemists have shown that this is due in part to a deficiency of the corn proteins in certain amino acids. They have shown that these acids are present in abundance in such materials as cottonseed, copra and peanut cake. Such materials added to corn should make of it an efficient feed. This has been demonstrated conclusively for one of the feeding stuffs derived from corn and inappropriately known as corn gluten. Upon a diet containing corn gluten alone as the only protein, a young animal will grow but slowly. If, however, as little as one-third of copra cake, which is cheaper than corn, be added, the animal will grow rapidly. With a suitable mixture of corn and such materials as copra cake or peanut cake it is possible to produce an optimum rate of growth with as little as 10 per cent of protein, the costly ingredient of the diet. The result is that a vastly smaller amount of feed need be used to produce a pound of live weight, while the time required is immensely shortened. What the application of principles like this means to the cost of producing meat and milk and what they mean to the mixed feed industry with an annual output amounting approximately to \$700,000,000 is obvious.

CHEMISTRY IN THE SUGAR INDUSTRY

Even the sugar industry, upon which chemists, in the creation of the beet sugar industry, have already exerted a profound influence, still presents a multiplicity of problems. It is by no means certain that sugar cane and sugar beets are the ideal sugar plants for all climates and soils. At least one other plant, the nipa palm, shows great promise, and there is no telling what of commercial value a systematic chemical survey of the vegetable kingdom would uncover. Moreover, sugar refining demands simplification so as to make possible the economical production of white sugar upon the plantation with all the economies in labor, transportation and handling therein involved. These, too, are problems that will be solved by the application of the principles of colloid, physical and biological chemistry, for they involve the removal from the sugar plant juices of colloidal materials and the control of enzyme action,

factors that are intimately connected with the formation of molasses, which the sugar house chemist usually endeavors to suppress.

CHEMISTRY IN THE INDUSTRIES UTILIZING SUGAR

There is a very great amount of work to be done in the industries that utilize sugar as their raw material, particularly the confectioner's industry. The going stale of candy is, in the majority of instances, merely the crystallization of the sugar. It should be possible by the application of the principle of physical chemistry to prevent most of these losses. Hard candies are boiled to a definite temperature mainly for the purpose of inverting a certain proportion of the sugar that they contain. This is, therefore, a more or less haphazard matter. If too little invert sugar is formed in the process of boiling the candy, the sugar will crystallize and the candy will rapidly become stale. If there is too much invert sugar formed, the candy will be hygroscopic and will become sticky in hot weather and not salable for these reasons. This is a very important problem to the confectionery industry and one that should be capable of solution by very simple chemical studies.

CHEMISTRY OF FOOD FLAVORS

Another carbohydrate industry that demands the attention of physical chemists is the manufacture of jams, jellies and preserves. The conditions for jell formations, for the inversion of the sugar, the preservation of the rich ripe flavor of fruit and the achievement of the best possible texture are all problems of colloid or physical chemistry to which practically no attention has been paid by properly trained men. It should be possible for such men to vastly improve the methods of producing these materials and to introduce very important economies and improvements in the processes. Indeed the whole matter of the chemistry of food flavors is one of tremendous economic importance, for food prices often depend not upon food value, but upon palatability. With a complete knowledge of the chemical nature of flavoring materials it would be possible to give to cheap but nourishing foodstuffs a high degree of palatability.

These problems are of the utmost importance to the canning industry since the retention in the preserved finished product of color, flavor and texture is one of the ends it is striving for. Moreover, containers and methods of sterilization have by no means been perfected. The prevention of the deterioration of canned goods, of the rusting and perforation of the cans, of the blackening and change in color of corn and other products—these are but a few of the problems that confront the chemical adviser to the canning industry. Some of these problems, no doubt, will be solved in part by abandoning canning as a means of preservation and substituting dehydration—a new and, at the moment, rapidly developing industry that presents to the chemist and the chemical engineer a host of its own peculiar problems.

IMPORTANCE OF BIOCHEMISTRY IN THE SOLUTION OF FOOD MANUFACTURING PROBLEMS

An innumerable number of examples might be cited to show what the chemist has accomplished in the food industry. Such examples have been avoided on the assumption that what has been done, as, for example, in the hydrogenation of oils, will be known to the readers of this journal. It seemed preferable to give a few

examples from the field that remain to be developed. It is evident from the examples given that these opportunities belong very largely to the biochemist and that future developments must follow the performance of fundamental laboratory research which, in this field as in any other, must precede practical application in the industry. Until recently the science of biochemistry has been cultivated only in medical faculties. Biochemistry in this and in other countries has been a hand-maiden to medicine. The time has come when a new type of biochemist must be developed who applies the principles and the technique of biochemical research to the problems of agriculture and the problems of the industries that use agricultural raw materials. The time has come when chairs of biochemistry should be found in technical schools as well as in schools of medicine.

The Arsenic Industry in Japan

Arsenic is found in Japan as an ore, as well as being a byproduct from the smelting of copper and lead, reports Vice-Consul Goodier of Yokohama.

Ore deposits are said to be fairly large in the Prefectures of Oita, Miyazaki, Hiroshima, Hyogo, Shimane and Okayama, their percentage of arsenic ranging from 15 to 30 per cent.

In 1918, 1,828,198 lb. of ore valued at \$9,204 was produced. The output increased to 2,133,281 lb. in 1919, but its value decreased to \$6,975. This did not include ore used at the mines by the companies for producing arsenious acid, or crude "arsenic."

Concerning this "acid" available statistics give the total production in 1918 as 877,651 lb. and 2,862,653 lb. in 1919. Its exact value is unobtainable but may be estimated from the declared export returns of consulates in Japan, excluding Taiwan and Dairen. The total export to the United States in 1919 is given as 1,821,340 lb. with a value of \$70,739, of which 1,387,388 lb., valued at \$48,337, was from Yokohama. The total export from Yokohama to the United States during the first seven months of 1920 is stated as 1,102,020 lb., valued at \$39,510.

METHODS OF PRODUCTION

Arsenious acid is produced in Japan by direct reduction of arsenic ore and also as a byproduct in copper and lead smelting. The former method has been used on a small scale for the last ten years, but only quite recently have byproduct methods been installed by certain copper and lead mining companies in endeavors to consume poisonous gases, etc., from smelting operations.

Under the direct method of producing arsenious "acid" one company is said to have a capacity of about 3,333 lb. at a firing. The charge is renewed about twenty times a month. From ore of 20 per cent arsenic the output of one furnace will make approximately 13,333 lb. of crude arsenic each month.

About 20 per cent is lost in refining.

The three largest manufacturers of arsenious acid in Japan are said to approximate a monthly output of seventy tons (crude only), thirty and fifteen tons (both refined), respectively.

The arsenic content of acid thus produced by both methods is, roughly, 95 per cent in the crude and about 97 to 99 per cent in the refined.

If the industry is given adequate support by large companies, it is claimed that 4,000 tons of acid per year can be produced from known sources.

Electric vs. Combustion Furnaces for Low Temperatures

Electric Furnaces Have the Advantage in Temperature Control, Reliable and Permanent Source of Heat, and Maintenance—Cost of Power Is Counterbalanced by Economy in Space, Auxiliaries, and Operation, While the Quality of Product Is Greatly Enhanced

By FRANK W. BROOKE AND GEORGE P. MILLS

AS A heating agent, electric energy was first used in a commercial way about fifteen years ago. The application made at that time was in a single-phase melting furnace. The development of the electric arc-melting furnace is well known. The application of electric energy to processes requiring low temperatures ranging up to 1,800 deg. F. (1,000 deg. C.) is more recent, but has now reached a state of perfection and during the last three years has made remarkable strides in the steel industry, many important large installations having been made during this period.

Probably one of the best means of explaining the salient points of an electrically-heated furnace is by comparing its characteristics with the characteristics of fuel-fired furnaces in general use. It is recognized that excellent results in the heat-treating field have been obtained by the use of various types of combustion furnaces, and it is our purpose not to minimize this development, but to emphasize the direction of the most recent progress.

PRINCIPLE AND DESIGN

An electric furnace, whether of standard or special design, consists essentially of a steel shell properly reinforced and supported. Against the shell is laid up an ample thickness of high-grade heat-insulating brick arranged in three or four courses with all joints broken. The furnace lining of firebrick is placed inside and bonded to the insulating brick. The heating element preferably consists of very rugged ribbon resistors hung on insulating brick, which are built into the firebrick lining.

The rugged construction of the electric furnace compares most favorably with the construction of the hearth, walls and roof of the combustion type of furnace, which are necessarily cut up by ports, flues, combustion chamber, etc. These openings, being subjected to the high flame temperatures, constitute one of the chief weaknesses in the construction of the combustion furnace. The elimination of these features not only allows the most rugged construction and requires the most limited floor space, but reduces the design of the electric furnace to a scientific problem. Known quantities are dealt with throughout.

On account of the simplicity of principle and design, the electric furnace lends itself admirably to many forms of construction. Some of the more common forms are:

- (1) Horizontal chamber type, in which the work is charged and withdrawn through the same door.
- (2) Vertical cylindrical type with top cover.
- (3) Horizontal tunnel type, in which the work is charged in one end and discharged at the other end.
- (4) Car bottom type.
- (5) Conveying type.
- (6) Recuperative type, in which the hot outgoing

work provides energy for preheating the cold incoming work.

CHARACTER OF HEAT

In the best type of fuel-fired furnace, the heat is generated by the combustion of the fuel with the oxygen of the air at a temperature far in excess of the actual degree required in the work to be treated. This heat is produced in a separate combustion chamber and has to be carried through a series of flues, false bottoms, double arches and port-holes, all of which absorb a considerable amount of useful heat. Even then there is a great element of uncertainty in distributing the heat uniformly over the material treated. Another phase to be considered is that, where the material to be treated is not all of uniform section, the result of the high temperature gradient is to overheat the thinner sections in order properly to heat the thicker sections. Gases leave the furnace at a high temperature, and even with the regenerative type of combustion furnace a large percentage of the heat developed is wasted.

Heat in the electric furnace is generated in resistor units distributed over the interior of the furnace, and may be produced at a temperature only slightly higher than that to which it is utilized by the work. This is important, as it eliminates the possibility of the surface of the work being overheated or burned while the inner masses are coming up to temperature. As no combustion takes place, no gas or air is blown through the furnace. On the other hand, the atmosphere in the furnace is dead or quiet, and full advantage is taken of penetrating, uniform radiant heat. The energy being confined, it is taken up by the work at the maximum rate at which the surface will conduct heat to the inner masses.

TEMPERATURE CONTROL

Accuracy and uniformity of temperature control are obtained in the electric furnace to a degree that cannot be produced in any combustion furnace. On a small furnace all of the heating elements are connected to the power supply circuit through one automatic control panel. In larger furnaces, or where the process requires two or more different temperatures in the same furnace, the processed material being conveyed through the furnace, the heating elements are divided into separately-controlled zones. It is an easy matter to provide a complete heating, holding and cooling cycle, with time and temperature automatically controlled for the complete cycle.

On account of the fact that the heating elements may be so distributed as to radiate additional heat energy in the zones subject to the greatest losses from radiation, excellent uniformity of temperature is maintained throughout the furnace. Temperature uniformity throughout the furnace within plus and minus 5 deg. F. is the usual condition obtained.

With any form of combustion furnace it is necessary to regulate the temperature by means of rate of firing, operation of dampers or valves, which means that the temperature control is entirely dependent upon the ability of and care taken by the operator. In the combustion type of furnace it is very difficult to arrive at a true indication of the temperature of the material to be treated, owing to the fact that there is a large difference of temperature between the source of the heat - namely, the flame - and the material to be treated, and also because the most usual location of a pyrometer tube is such as causes the gases to impinge upon it, which again gives an erroneous reading, both of them higher than the true reading of the work itself.

It is also a very common practice, especially in the steel industry, to "soak" the steel to be treated. This practice of soaking in combustion furnaces is usually a matter of playing safe, because there is no true method of ascertaining when the steel itself is at the correct desired temperature for the heat treatment, and the length of soaking is invariably decided on from past experience, always at the expense of the amount of fuel required per ton of steel to be treated. There is also a practice of going to a higher temperature than is really necessary, for the same reason, as the metallurgist wishes to make absolutely sure that he has gone above the recalescence point of the particular steel he is treating.

The electric furnace fulfills two very desirable objects, the first being that with first-class recorders the true point of soaking can be determined as soon as it is reached. The recorder also shows not the temperature of the furnace nor the temperature of any impinging flame, but the true temperature of the work itself, and if the metallurgist requires a very fine grade of steel for any particular purpose he may go just as near to the recalescence point, with perfect safety, as he desires.

FUEL COMPARISONS

Oil as a fuel, especially under present-day conditions, has the following objections: It requires in proportion a very large amount of air, quite a lot of which, unless the furnace is of the muffle type, comes in contact with the material to be treated, and if this material is of an oxidizable nature it will scale. Other materials, such as enamel, may be affected or completely destroyed by contact, not only with the air, but also with the oil or products of combustion. If these features are to be avoided in combustion furnaces, muffle types of furnaces have in a good many cases to be resorted to, or else the material has to be packed with some packing material in boxes, both of which very seriously affect the thermal efficiency of the furnace and thereby the cost of fuel.

Natural gas in nearly all its present fields has to be supplemented, during certain parts of the day, by artificial gas, which at once lowers its heating value. This occurs at the time that most manufacturers require the greatest supply and, because of this demand, artificial gas has to be supplied to the main, thereby reducing its heating value at a time when it is most needed.

One of the most important political questions in the world today is to assure an adequate supply of oil for the future. Some of the figures published by the Government must give every manufacturer serious consideration for the future. In addition to this, the supply is also subject to a good many economic con-

ditions, such as strikes, embargoes, car shortages, for which there is only one practical solution to the individual manufacturer, which is to put in a very large storage capacity. This calls for a high first cost installation and automatically increases the seriousness of the congested condition.

In the case of coal, while our future supply is undoubtedly adequate for some time to come, the same economic conditions exist.

In the case of electricity as a fuel, the manufacturer need not have any consideration for storage or future supply. The storage is taken care of for him by the large public utility companies, which by their charter, have first priority on fuel supplies, and the wonderful water-power resources have been tapped only to a small extent.

ITEMS TO INCLUDE IN FIRST COST

In comparing the first cost of heat-treating furnaces, the purchaser often compares the cost of the furnaces only. This is decidedly unfair toward the electric furnace, and a true comparison can be made only by figuring up the total first cost, not of the furnaces, but of the complete installation. Thus, in an oil-fired furnace, it is only fair to figure in the cost of storage tanks, the cost of all the piping and the cost of the blowers or compressors, as the case may be, for the air supply, and, in a good many cases, new railway sidings. In the case of coal and other fuels, it is often necessary to put in new or additional sidings, or to have trestle work, supply bins or cranes, together with handling apparatus.

The space occupied by any type of combustion furnace for a given tonnage of material to be treated per day is very much larger than any type of electric furnace. When to this is added the extra space that is always required by combustion furnaces for their auxiliaries, such as storage tanks, siding, compressor rooms, ash disposals, etc., the comparison should be given very serious consideration.

MAINTENANCE

Four or five years ago, in discussing electric furnaces of the resistance type, one of the most usual questions was: What is the life of the heating units? And the makers of the electric furnaces had to reply in terms of hours, such a thousand hours or two thousand hours, as the case may have been.

With the remarkable progress made, however, during the last three years, this has been entirely eliminated, and the life of a heating unit today may be stated to be indefinite, as heating units that have been in operation for over two years on a commercial basis, day in and day out, are still as good today as the day they were installed, and their only source of breakdown would be mechanical, when the furnace is of a poor design. The refractory lining of an electric furnace has a remarkably long life. This is because of the principle on which the furnace works, whereby the temperature of the heating units is only slightly above that of the temperature desired, and for all purposes where the electric furnace of the ribbon resistance type is used the temperature is so well within a safe limit for refractory material that there is no burning out of the bricks in the furnace.

This is not the case in combustion furnaces, where high local temperatures and impinging of the flame on such parts as baffle walls, flues, portholes, etc., cause a

very serious wearing out or breakdown of the brick lining. In the case of oil, too, there is always a lot of mechanical maintenance, due to either dirt in the oil or, during the cold weather, the oil being very heavy and choking up small parts so necessary in this type of installation. Whereas, in the case of electricity, once the busbars and wiring are installed the flow of electricity is absolutely constant.

COST OF OPERATION

There is one correct way in which the cost must be figured in order to arrive at a true conclusion. This is to figure the total cost of a given process per unit of salable output. The total cost must include overhead—such as taxes, interest and depreciation—which vary with the initial cost of the installation and its lasting qualities; factory space occupied; repairs and maintenance; cost of fuel, including all labor incident to the handling of the fuel and disposal of ashes and refuse.

When the total cost per day or per week is arrived at by including all of the above items, it should be divided, not by the total number of units produced by the furnace, but by the number of units which pass inspection.

It is most unfair to compare, as is often done, the cost of electricity with the cost of oil or coal on the car. With the electric furnace the heating agent—that is, the electric power—is measured by meter at the control panel and the total cost of the “fuel” is the number of kilowatt-hours used, times the rate. With the coal-fired furnace expensive labor is used from the time the coal car is placed on the siding until the ashes are placed on the dump. With the oil-fired furnace labor is necessary for the keeping of the oil storage, pumps, piping and burners in good operating condition.

High temperature gradient is not necessary in the electric furnace. The repairs and maintenance on the electric furnace, therefore, are negligible. With the oil- or coal-fired furnace, temperatures up to 3,000 or 3,300 deg. F. (1,700 deg. C.) must be taken care of in the combustion chamber and flues. The maintenance of these parts of the combustion furnace, therefore, is quite an item and must be figured.

Space occupied by the electric furnace is always less than that occupied by a combustion type of furnace. When the fuel storage capacity required by the combustion type of furnace is considered, the comparison is greatly in favor of the electric furnace. This is an item to be considered in the cost of operation.

Due to the remarkable temperature control and uniformity of heating obtained in the electric furnace, rejections due to spoiled work have always been less in the electric furnace than in any combustion type of furnace. In some classes of product very few rejections will double the cost of the heat-treating process.

The cleanliness surrounding an electrical installation of any type is too well known to require description. The high degree of insulation and the remarkable degree of thermal efficiency which can be maintained in the electric furnace result in a clear surrounding atmosphere that is never higher than the normal temperature of the shop—a feature worthy of consideration. Voltage on the furnaces is never of high order. In most furnaces arrangements can be made where the current, and thereby the heat, is automatically cut off as soon as the doors begin to open. There is no danger from ex-

plosions or “gassing,” and from the safety engineer's point of view these installations are ideal.

SUMMARY

The advantages of the electric furnace over combustion furnaces may briefly be summarized as follows:

1. Absolutely automatic temperature control.
2. Saving in labor—no handling of coal, ashes, oil, storage, pumps, etc.
3. Upkeep cost, so small as to be inconsiderable.
4. Saving in space occupied.
5. Large saving in costs due to reduction of rejections in finished product.
6. Improved product.
7. High thermal efficiency.
8. Ideal shop conditions.

Philadelphia, Pa.

South African Trade in Soap

The total amount of common and brown soap imported into the Union of South Africa in 1913, a pre-war year, was 6,626,476 lb., valued at \$273,331, says Consul General George H. Murphy of Cape Town in *Commerce Reports*. The principal countries supplying this soap were the United Kingdom, 5,508,884 lb., valued at \$224,681; Australia, 857,171 lb., valued at \$37,326; and the United States, 213,169 lb., valued at \$8,145.

In 1918 the total imports amounted to 725,692 lb., valued at \$63,460. This was supplied as follows: United Kingdom, 172,843 lb., valued at \$15,558; Australia, 154,142 lb., valued at \$9,868; and the United States, 369,179 lb., valued at \$34,892. The total exports in 1918, consisting almost entirely of domestic produce, amounted to 3,112,966 lb., valued at \$317,325. Most of these exports went to contiguous countries in the following proportions: Madagascar, 1,162,845 lb., valued at \$109,077; Southwest Protectorate, 723,441 lb., valued at \$14,488; Portuguese East Africa, 337,744 lb., valued at \$35,374; Belgian Congo, 258,144 lb., valued at \$30,921; British East Africa, 242,299 lb., valued at \$27,290; and Zanzibar, 222,437 lb., valued at \$23,694.

This decrease in the imports and the large increase in the exports are due almost entirely to the establishment in South Africa during the past few years of several large soap manufacturers, among which are Lever Bros. (Ltd.), of England, which now has a practical monopoly of the laundry-soap business in South Africa. This soap retails for 1s. 9d. (42c.) for a package of six cakes, each cake being approximately 1 x 2½ x 3 in. in size.

The customs duty in the Union of South Africa on imported laundry soap is 4s. 9d. (\$1.14) per 100 lb. or 25 per cent ad valorem, whichever duty shall be the greater. A rebate of 7d. (14c.) on each 100 lb. or 3 per cent ad valorem, as the case may be, is granted on the product or manufacture of the United Kingdom or reciprocating British colonies.

While the market is limited and will be even more so with the growth of the domestic industry, the only possible way in which to reach it would be by a great amount of advertising and by placing an agency in the hands of a progressive manufacturers' agent. Such manufacturers' agents often cover the whole Union, calling upon the entire wholesale trade. In placing products with one wholesale house this often restricts the business to the clientèle of that particular house, as most of the wholesalers prefer to have exclusive agency rights in the products that they handle.

The Fundamentals of the Electrolytic Diaphragm Cell*—I.

Detailed Study of Brine Composition and Products During Electrolysis in Diaphragm Cells—Current, Decomposition and Energy Efficiencies—Pounds of Caustic Soda Diffused per Sq.Ft. of Diaphragm per Hour Into Saturated Brine at Varying Decomposition Efficiencies

BY HUGH KELSEA MOORE

IN 1897 E. A. Allen and H. K. Moore introduced a cell in which was claimed the basic principle of having the cathode unsubmerged in the electrolyte. During the twenty-three years which have elapsed since this time this principle has revolutionized the entire cell industry in the United States.

The first experimental cells built had horizontal diaphragms submerged in a bath of kerosene oil and the caustic as it was formed on the cathode sank to the bottom of the oil and was siphoned off from the bottom. On account of danger of fire, experiments on this line were discontinued and the experiments were conducted having the cathode unsubmerged in the electrolyte but with no oil to balance the static head of the liquor in the anode compartment. Owing to the importance which the unsubmerged diaphragm cell has assumed in the electrolytic industry, it might be well to discuss the fundamental principles involved.

In order that there may be no misunderstanding in regard to the unsubmerged diaphragm cell, I wish to mention that one type of cell represented by the Hargreaves-Bird cell, used for the production of carbonate of soda and chlorine, had an unsubmerged cathode. This type of cell, however, was not available for the production of caustic soda and so far as I know has never been capable of producing caustic soda. In this cell the diaphragm was so impregnated as to prevent the percolation of the electrolyte. The unsubmerged diaphragm type of cells to which I refer allows the electrolyte to percolate through the diaphragm.

Suppose we start with the fundamentals. If a com-

partment filled with salt brine is divided into two parts by a permeable diaphragm and an anode is inserted in one compartment and a cathode in the other and a direct current is passed through, we have chlorine liberated at the anode and caustic soda liberated at the cathode according to the following equation:

If the passage of the current is continued, we obtain an electrolyte constantly decreasing in percentage of salt and constantly increasing in percentage of caustic soda. There will also be a slight increase in the percentage of water in spite of the fact that water is used up in the production of caustic soda. This is due to loss of chlorine which overbalances the loss of water. (See Table I and Fig. 1.)

In Fig. 1 it will be noticed that the term "Decomposition Efficiency" has been used and in order to prevent any misconception of terms, the author's own definitions are included throughout. Therefore this article should be read and criticised in accordance with them and not by any other definitions with which the reader may have previously been familiar.

CURRENT DECOMPOSITION AND ENERGY EFFICIENCIES

A given number of amperes will theoretically produce a given amount of caustic soda in a given time. (See Appendix.) The amount of caustic actually formed, divided by that which should be theoretically formed, is the current efficiency. For example, 303 amp. will produce 1 lb. of caustic per hour. Consequently if we have 1,212 amp. running through a brine solution for one hour and actually obtain 3 lb. of caustic soda, we have

$$3 : 1212 \quad 75 \text{ per cent current efficiency.}$$

Decomposition efficiency is the percentage of the salt actually decomposed. Suppose a given sample of caustic effluent takes 6 c.c. of N/10 H_2SO_4 and 4 c.c. of N/10 AgNO_3 , we have $6 : (6 + 4) = 60$ per cent decomposition efficiency. There is a certain theoretical voltage required for the electrolysis of every electrolyte and any excess of voltage above the theoretical voltage means lost power. For example, we may consider the electromotive force required to electrolyze salt and water into caustic soda, chlorine and hydrogen as 2.3 volts. (See Appendix.)

Now if a cell runs at a current efficiency of 75 per cent with a voltage of 4.1, we have an energy efficiency of $(2.3 : 4.1) \times 75 = 42.7$ per cent energy efficiency or power efficiency. That is, the energy efficiency is obtained by dividing the theoretical energy required to produce a certain amount of product by the energy actually required to produce that amount of product. Or in other words, the energy efficiency is the percentage of power actually used which is represented by production.

The commercial cell plant endeavors to use a satur-

TABLE I. PRODUCTS RESULTING FROM ELECTROLYTIC DECOMPOSITION OF 26 PER CENT BRINE SOLUTION

*Read before the American Institute of Chemical Engineers, Montreal, June 28, 1920.

ated brine for reasons hereinafter explained. Complete saturation, however, is rarely reached, but it is practical to obtain a brine of 99 per cent saturation or a brine containing approximately 26 per cent salt.

Table I, illustrated graphically by Fig. 1, shows the varying percentages of caustic soda, salt and water resulting from the electrolytic decomposition of a brine solution containing 26 per cent salt. These figures are theoretical, for they make no allowance for the small amounts of water evaporated according to the energy efficiency of the cell, for it will be readily seen that the less the energy efficiency of the cell the greater is the amount of heat generated in the cell and consequently the greater the amount of evaporation, provided of course that this is not compensated for by external cooling. The abscissæ show the per cent decomposition efficiencies and the ordinates the varying composition percentages of salt, caustic soda and water.

Fig. 1A shows this in a different manner on a three co-ordinate chart, all values lying on the straight line AB. Fig. 1B shows the weights in grams of different chemicals, present or formed, in terms of decomposition efficiencies, obtained by electrolyzing 100 g. of a 26 per cent salt solution. Now as the caustic soda increases in strength there is a tendency for this to diffuse by osmotic pressure into the anode compartment.

DIFFUSION THROUGH DIAPHRAGMS

In Table II, illustrated graphically by Fig. 2, will be seen the pounds of caustic which will diffuse through a square foot of diaphragm in an hour with a 26 per cent salt solution from a brine containing different percentages of caustic soda and salt according to the decomposition efficiencies on Fig. 1.

The solid line shows the pounds of caustic per sq.ft. of diaphragm which will diffuse from cold solutions of salt and caustic according to decomposition efficiencies (see Table I) into a 26 per cent brine solution. The temperature of both solutions is 70 deg. F. There is no static head of one solution over the other. While these figures will undoubtedly vary according to the nature of the diaphragm, yet they represent well-known tendencies. These figures are also taken from asbestos such as is used in practice in making diaphragms.

It will be seen from Fig. 2 that the diffusion of caustic into the anode compartment increases very rapidly with the concentration. In order to lessen this diffusion of caustic in cells of the submerged diaphragm type it has been customary to keep the brine in the anode compartment at a higher level than in the cathode compartment, thus retarding the inward diffusion of caustic by the outflow of brine. In addition to the above it has been customary to reduce the concentration of caustic in the cathode compartment by the addition of water. This adds to the evaporating cost, but more than compensates for this by increasing the efficiencies of the cells and reducing the loss of the carbons. I think we can illustrate this loss by the following equations which take place in the anode compartment:

The sodium hypochlorite may be electrolyzed as follows:

It will be seen that this nascent oxygen attacks the carbons with the formation of carbon dioxide and heat. Thus we have a serious waste of carbons as well as a loss of power.

The diffusion of caustic also tends to increase as the temperature rises. See Table IIA, illustrated by the broken line on Fig. 2.

The broken line shows the same factors as the solid line, with the exception that the caustic solution is at

TABLE IIA

Lb. NaOH Diffused per Sq.Ft. of Diaphragm per Hour Into 26 per Cent NaCl at Varying Decomposition Efficiencies

Per Cent Decomp. Eff.	Temperature NaOH, 120 Deg.; Temperature NaCl, 74 Deg.									
	11.2	20.0	30.3	39.9	49.9	59.8	69.9	79.6	89.8	
Lb.	0.0254	0.0566	0.0758	0.0937	0.1237	0.1591	0.2113	0.2483	0.3024	

120 deg. F. instead of at 74 deg. F. The brine temperature has been kept at 74 deg. as in the first case mentioned. It will be seen from this curve that a rise in temperature in the cathode compartment increases markedly the rate of diffusion of caustic into the 26 per cent brine solution. To illustrate this tendency still further I submit Table IIB, illustrated by the dotted line in Fig. 2.

The dotted line shows the same factors as the solid line, with the exception that both the caustic and brine solutions are kept at 120 deg. F. It will be seen from

TABLE IIB

Lb. NaOH Diffused per Sq.Ft. of Diaphragm per Hour Into 26 per Cent NaCl at Varying Decomposition Efficiencies

Per Cent Decomp. Eff.	Temperature NaOH, 120 Deg. Temperature NaCl, 120 Deg.									
	10.0	19.4	30.2	40.0	49.8	59.0	70.5	80.3	89.9	
Lb.	0.0451	0.0765	0.0968	0.113	0.147	0.229	0.258	0.293	0.346	

the above that anything which tends to reduce the temperature tends to slow down the diffusion of caustic. Cells with submerged diaphragms should not be insulated against loss of heat.

I might add that the addition of water to the cathode compartment of a submerged cathode cell tends to lower the temperature of the cathode electrolyte and thus also tends to check this diffusion from this cause in addition to checking the diffusion by lowering the concentration of the electrolyte.

INTRODUCTION OF ACHESON GRAPHITE ELECTRODES

It must not be thought from what has been said that the losses caused by diffusion of caustic into the anode compartment ended with those mentioned. In the old days gas-retort carbon was the only carbon available for electrolytic purposes, as Acheson's remarkable product had not then been invented. I might add that, as far as I know, I was the first user of Acheson's graphite in

TABLE II.

Lb. NaOH Diffused per Sq.Ft. of Diaphragm per Hour Into 26 per Cent NaCl at Varying Decomposition Efficiencies
Temperature of Both 74 Deg.

Per Cent Decomp. Eff.	5	10	15	20	25	30	35	41	50	60	70	75	85	97
Lb.	0.004	0.0085	0.013	0.017	0.026	0.037	0.055	0.062	0.080	0.105	0.138	0.142	0.181	0.188

electrolytic cells. The retort-gas carbon anodes used prior to Acheson's invention were rapidly attacked by the nascent oxygen liberated on them and the mixture of carbon dioxide and chlorine went to bleach chambers, where the carbon dioxide, having a greater affinity for the slaked lime than the chlorine, liberated chlorine from the bleach already formed. In order that the bleach should not test below 35 per cent available chlorine, it was necessary to skim the carbonate of lime crust formed on the top of the bleach from the bleaching powder underneath.

Thus, you see, this diffusion of caustic caused not only a waste of electrolytic carbons and power but it also

caused a waste of lime, chlorine and labor. There were also other losses, but I will not go into them here. Graphite carbons are also attacked by the nascent oxygen liberated thereon, though not to the same extent that gas carbons are attacked.

Realizing all these difficulties, Moore and Allen attempted to do away with this diffusion by allowing the caustic to run away as fast as formed, either through oil or otherwise.

RATE OF FLOW

In experimenting with different cells it was noticed that sometimes the current efficiency of a cell starting

Current and decomposition efficiencies at lower ranges.

up was somewhat lower than after the cell had been running a day or two. It was also noticed that as the cell got older the current efficiency generally rose for a short period, after which the current efficiency gradually declined. These results were not apparent at first because they were obscured by a varying current. In studying the reasons for this we tried to adopt a standard unit of measure by which the operation of two cells might be compared, irrespective of their ages, sizes and the current passing through them. C. B. Barton suggested the measure which we now term as the Rate of Flow and Mr. Barton and Mr. Moore, working independently, made many experiments developing this measure so that they had absolute control of the efficiency of any cell. The pounds caustic solution per ampere hour per square foot of diaphragm was called the Rate of Flow. Since then this term has been broadened to include volume as well as weight. The tabulation and plotting of results showed that when the rate of flow was large the current efficiency was low because of the large amount of chlorine dissolved in the brine, which on passing through the diaphragm with its equivalent amount of caustic and hydrogen re-forms salt and water with the liberation of heat. As the rate of flow diminished the amount of chlorine passing through the diaphragm diminished and the current efficiency rose to its maximum. As the rate of flow continued to diminish the current efficiency diminished and continued to diminish. I should like to be able to submit the original tables and charts illustrating this fact, but cannot do so, as they were destroyed by fire.

Table III, illustrated by Fig. 3, gives an idea of one form of rate of flow—viz., c.c. outflow caustic liquor per amp. hour per sq.ft. of diaphragm.

Table IV, Fig. 4, shows a chart of a cell in which the abscissæ represent consecutive days and the ordi-

nates represent the per cent current efficiency, per cent decomposition efficiency, per cent power efficiency and the current in amperes and volts. It will be seen that a chart of this sort requires considerable study before much information is obtained.

Some of the facts shown in Table IV, illustrated by Fig. 4, are shown in Table III and Fig. 3.

It will be seen from the above that we get very regular curves from the apparently heterogeneous matter, as shown in Fig. 4.

Table V, Fig. 5, shows some of the lower ranges. This is only of academic interest, as cells are not supposed to run commercially in a manner to give such results. Of course the results as given in Table V were obtained solely to get some idea as to what effect the continued drop in rate of flow would have.

It will be noticed that Fig. 5 has different characteristics from Fig. 3. In Fig. 5 the cell was run on impure

brine. It will be seen from the above that while the rate of flow chart is very valuable for comparative purposes when conditions are alike, care must be taken not to use the rate of flow chart determined under one set of conditions to interpret results of cells run under radically different conditions.

Of course neither these results nor the above are absolute, as they may vary within certain limits as will be seen later.

In the above it will be seen that I have given number of c.c. per amp. hour instead of lb. per amp. hour. This is more convenient, inasmuch as one can use a graduate instead of a set of scales.

The application of this kind of chart to the operation of a cell plant is a very simple matter. Suppose, for instance, you found you are going to have available in your cell plant 1,000 amp. and each cell has 20 sq.ft. of diaphragm and that you wished to run at 50 per cent decomposition efficiency. You would look up the rate of flow in c.c. per amp. hour per sq.ft. of diaphragm for 50 per cent decomposition efficiency, which according to Fig. 3 would be 0.46; multiply by 20 and 1,000 and you have 9,200, the number of c.c. per hour which must run through the cell to give you your desired results. If, however, all your cells had the same number of sq.ft. of diaphragm you could make a table like Table VI,

illustrated by Fig. 6, and thus avoid the extra calculation.

Fig. 6 is based on a cell having 26.5 sq.ft. of diaphragm.

Suppose you had a cell plant each cell of which had 26.5 sq.ft. of diaphragm and you wished to run at 55 per cent decomposition efficiency with 1,200 amp. current; you would tell the operator to regulate the levels of the brine in the cells so that he would obtain a flow of 216 c.c. per minute—viz., rate of flow at 55 per cent decomp. — 10.8 c.c.

$$(10.8 \times 1,200) : 60 \text{ (min. per hr.)} = 216 \text{ c.c. per min.}$$

At this decomposition efficiency the cell should have a current efficiency of 93 per cent. It will be seen from the above curves that a cell plant cannot be regulated by the amount of brine fed to the whole plant, for the cell which has too great a flow will have a low efficiency as well as the cell which has too small a rate of flow. To run a cell plant properly each cell should be regulated as to its rate of flow individually. In a commercial plant you have a mixture of cells whose ages since renewal of diaphragms, carbons, etc., may vary all the way from one day to 300 days. In our plant of 550 cells the ages vary from one day to 180 days.

Automatic Cooking Control for Chemical Pulp*

BY C. H. ALLEN

SULPHITE pulp should be cooked automatically for three principal reasons, as follows: (1) Production will be increased; (2) quality will be improved; (3) the steam load on the boiler house will be more uniform.

The automatic control which I shall describe does for each charge of chips what a good cook tries to do but can never do, because, in the first place, the apparatus he is using places a practical limit on his control, and secondly, he cannot be everywhere at once and think of everything at the same time.

The Allen automatic cooking control system consists essentially of a power-driven steam valve electrically connected to a steam flow meter on the digester steam line, an automatic relief valve, and relief strainers that do not plug. It also includes the automatic separation of relief gas and liquor.

The steam apparatus can be set to maintain any constant or varying steam flow curve. Temperatures within the digester are proportional to the rate of steam input. The control apparatus therefore can be set to give any desired temperature curve.

Cooking automatically does not necessarily mean that all charges of chips will be steamed on the same steam curve. In practice, where the strength of the acid and quality of chips are reasonably constant the same steam flow curve should be used on all digester charges; but in cases where the strength of acid and quality of chips vary widely from cook to cook better results may be obtained by varying the form of the steam curve to suit changing conditions.

These changes in the steam flow curve are very readily and quickly made. The steam curve element of the control system is a small thin plate of copper having an

insulated hole; it is slipped over the chart spindle of the steam flow meter clock. The periphery of this piece of copper at any point represents the rate of steam it is desired to carry at that particular instant.

Once the cook is started it needs no further attention until blowing time, and further, when a cook is started it is known beforehand when it is going to blow, within a few minutes. The reason for this is that it takes a certain and very definite quantity of steam to cook a cord of chips, and steam is metered into the digester at a predetermined rate. The cooking time may be shortened by steaming at predetermined higher rates, and lengthened by steaming at predetermined lower rates. It has been proved that other conditions such as will occur from day to day do not affect the cooking time except to a negligible degree. When the digesters of any one mill are steamed automatically, the proper spacing out of the blowing time follows as a natural and inevitable result. If as sometimes happens after blowing a digester a small amount of repairs are found necessary to the blow valve or piping, which delays the time of starting to cook the next charge of chips, the cooking operation can nevertheless be finished on schedule time by adjusting the control apparatus to maintain a higher steaming rate.

The automatic relief valve can be set to maintain any pressure it is desired to carry within the digester. The relief valve stem is operated by a diaphragm which carries digester pressure on one side and is counteracted by a spring on the other. The diaphragm and spring are made large so that the resistance due to the sticking of the valve stem in its packing is practically negligible in comparison with the forces which tend to actuate the valve. When cooking by hand a good cook tries to open his relief valve by very small amounts at each adjustment and just enough to hold the digester pressure against his steam valve opening. If he happens to open too wide the strainer plugs, it is then necessary to shut off steam, blow back the strainers and start over again. The automatic valve cracks open

*Read before the Technical Association of the Pulp and Paper Industry at the fall meeting in Saratoga Springs, N. Y., Sept. 1, 1920.

by exceedingly small increments. It is always open to the correct amount and instantly responds to changes in pressure too small for a cook to detect even if he happened to be trying to do so.

The strainers used in connection with the control apparatus are of two different designs, one being adapted for use under the cover and the other in the digester neck. The cover strainer, so called, is somewhat similar in appearance to other strainers in general use. It consists of a bronze internal framework and an outside covering of thin perforated lead. The neck strainer so called is made of perforated hard drawn lead. It is cylindrical in form and wide open at both ends. The outside diameter of this strainer is approximately 1½ in. less than the internal diameter of the digester neck. In short, the strainer is a perforated lead bushing fitting loosely in the digester neck. In operation the relief gas and liquor flow from within the strainer outwardly to the space between the bronze sleeve in the digester neck and the strainer, thence through the digester neck and through a pipe of suitable size to the automatic relief valve. This is a stationary

uniformity of quality than is the case where steaming is left entirely in the hands of the attendant. Temperature recorders give only a rough indication of the steaming rate. It is easily possible to produce a very smooth temperature curve and a very erratic steam flow curve at the same time.

Temperature recorders are sluggish and slow to respond to the throttle valve. They do not indicate the rate of steam input at any instant. Changes in the

FIG. 2. STEAM FLOW TO DIGESTER METER RECORDS
Top—Hand control. Middle—With well-known regulator. Bottom—With Allen automatic control system.

quantity of steam pouring into the digester can be detected by means of the temperature recorder only after the lapse of considerable time.

Moreover, the temperatures at any two points within the digester are seldom the same. This fact is illustrated by the three sets of temperature records shown in Fig. 1. These are records of actual cooks. The dotted line in each case is the temperature in the side of the digester. The solid line is the temperature in the head.

Violent changes in the steam rate of short duration cause scarcely a ripple in the temperature curve; however, spasmodic and violent changes in the rate of steaming do cause non-uniformity of product. Spasmodic and violent changes in the rate of steaming also affect the economy of steam plant operation disastrously.

A sulphite cook, whose experience in cooking sulphite extends back over a period of seventeen years, once said to me: "I never steam two digesters alike, and no two cooks steam digesters alike." This man spoke the truth, as the evidence of the temperature records indicates.

In Fig. 2 the first three curves are the steam flow meter records of three cooks steamed by hand. The next three curves are the actual steam flow meter records of three cooks steamed with a well-known regulator; these are even worse than the records from hand control, though to be fair it should be said that this regulator produces a very smooth pressure curve. However, the degree of smoothness of the pressure curve is no indication of quality or the cooking time.

The last three curves are actual steam flow records taken from the same digester when steamed automatically. The first two curves were produced with the apparatus set for a 10½-hr. cook, the last curve with the apparatus set for an 8½-hr. cook. The quality of sulphite produced by these automatically maintained steaming rates was excellent.

In general it may be stated that the form of the steam curve determines quality, and the average rate of steaming determines the length of the cook.

FIG. 1. DIGESTER TEMPERATURE RECORD

strainer—i.e., it is not removed when the digester is being refilled.

In the cooking of sulphite pulp many mill superintendents seek to have their cooks follow predetermined temperature curves. This practice represents an effort in the right direction and results in a somewhat greater

Steel Rails From Sink-Head and Ordinary Rail Ingots—III

Various Physical Tests, Metallographic Examinations and Chemical Surveys, as Usually Performed, Were Made Upon All the Rails Under Examination—Comparison Rails Performed Much Better Under the Drop Test, and Service Tests Report Less Abrasion*

By GEORGE K. BURGESS†

MECHANICAL TESTS

THE mechanical tests included the ordinary drop test made on the first 5-ft. piece below the top of the ingot showing physically sound steel. For the Hadfield rails this location was, in all but two cases, determined by the junction of sink-head with the ingot proper. The test was made in the usual way by dropping a 2,000-lb. tup from a height of 18 ft. upon the head of the rail, which was supported at two points 3 ft. apart. This test gives record of permanent set, elongation on the base and the number of blows required for the destruction of the rail.

The 6-in. test pieces (B, C, D, etc.—Figs. 1 and 2)*, the drop test pieces and the specimens from the "M-A" position were examined for ultimate tensile strength, using a 2-in. test length, yield point, elongation, reduction of area, and hardness of Brinell and scleroscope. All specimens for the tension tests were cut longitudinally.

Method of Expressing the Results of Mechanical Tests. It is thought best to express measurements, such as yield point, ultimate tensile strength, elongation, etc., in terms of the average and average deviation from the mean.

The deviation of a single observation is the amount by which that observation departs from the mean or average value. By subtracting each observation from the mean without regard to sign, and averaging these, the average deviation from the mean is obtained.

When using the usual method of expressing results of this kind in terms of maximum and minimum values, undue emphasis is placed upon the occasional widely divergent figure, while the very close agreement that may exist is not brought to light.

Ultimate Strength and Yield Point. The ultimate strengths of the steel in rails from the H and M ingots are given in Table VIII* and are of the same order of magnitude—about 125,000 lb. per sq.in. For the thirty-five sink-head ingots the non-uniformity, expressed as the average deviation from the mean for values at the "A," "B," "C," "D" and "E" positions, is somewhat greater than for the comparison ingots, except for the "A" position, at which the results are erratic.

If we consider the ultimate strength throughout the length of the ingot, we note for the sink-head ingots there is practical uniformity down to the "E" position, while in the comparison ingots there is an abrupt increase in ultimate strength from the "A" to the "B" position and then a gradual falling off until the bottom of the ingot is reached, where at the "F" position the ultimate tensile strength is about 9,000 lb. per sq.in. less than the maximum at "B."

If the comparison ingots are studied by groups corresponding to heats, it may be shown that the ultimate strength of each group may be distinguished from the others. Thus groups M1 to M5 and M6 to M10 run closely parallel through the ingot, with M6 to M10 having slightly higher ultimate strength. Group M11 to M15 is characterized by the abnormally high value approximately (130,000 lb. per sq.in.) in the "A" and "B" positions.

The yield point shows, in general, characteristics similar to the ultimate strength; for the former, however, there is a somewhat greater uniformity throughout the ingot for all types, and for the ingots of a given group. The sink-head ingots have a slightly higher yield point (62,370 lb. per sq.in.) than the comparison ingots (61,370 lb. per sq.in.). For the three groups of the latter there is a falling off throughout the length of the ingot from approximately 64,000 lb. per sq.in. for B rail to 59,000 lb. per sq.in. for F rail (as for the ultimate strength), while for the sink-head ingots the yield point remains practically constant throughout.

Elongation and Reduction of Area. The distribution of ductility, as measured by elongation in tension test pieces from rails through the length of the sink-head ingots, is somewhat more uniform than for the comparison ingots. Elongation is practically the reciprocal of the tensile strength.

The average elongation of the rails from the sink-head ingots is 13.8 per cent, of the comparison ingots 13.6 per cent; the reduction of area for the former type of ingot is 24.38 per cent, for the latter type 25.78 per cent with a range of 21.73 per cent at "B" to 31.68 per cent at the "F" position. There are also considerable differences among the three groups of comparison ingots.

Hardness. The scleroscope hardness numbers do not appear to have any significance in defining any differences in qualities or properties in the steel of the several ingots. The material from the sink-head ingots has an average hardness of 31 while the steel from ingots cast in the usual manner has an average hardness of 32.

The Brinell numerals are, as would be expected, fairly closely proportional to the ultimate strengths and they appear to follow even more exactly the yield points. Whether or not there is any definite relation between carbon segregation and Brinell numerals appears difficult to say. The holes in drilling for the former are $\frac{1}{2}$ in. in diameter and not always exactly coincident in location with the Brinell impression. In a general way one would expect the two to bear some relation to each other. The rails from the sink-head ingots had an average Brinell hardness of 260 (deviation ± 8) while the rails made from ingots cast with the small end uppermost without sink-heads had a Brinell hardness of 250 (deviation ± 6).

FIG. 7. RAIL H16-A

Sulphur print shows slight segregation in rail from upper part of ingot.

A—Shows eutectoid structure of slightly segregated streak in web.

B—Average fine grained structure, pearlite with a very slight trace of ferrite.

Drop Tests. In the drop tests, blows were given on head of rail to destruction, the deflection was measured for each blow, the elongation for each inch over 6 in. and the total elongation noted.

The drop-test piece was taken from near the top of the ingot and in each case was the first 5-ft. length of rail immediately after reaching physically sound steel—i. e., free from pipe—and in the case of the rails from sink-head ingots also below the bottom of the sink-head. Of the fourteen comparison rails none broke under four or five blows (six rails were nicked and broken after the fourth or fifth blow), while for the thirty-five Hadfield rails the range was two to seven blows, there being nine of four blows, and four of three blows; only twenty-two, or 63 per cent, of the rails from sink-head ingots withstood four or more blows. The ductility as measured by the deflection and elongation is also somewhat greater and more uniform for the comparison rails.

Recalling the greater uniformity of the sink-head over the comparison ingots as shown in nearly all other mechanical tests, in less segregation, greater homogeneity as shown by sulphur prints and etching, less amount and variability in discard to sound steel, the question of the significance and interpretation of the drop test may, it would seem, be raised with propriety. The greater ductility and more uniform behavior under the drop test of the steel from the comparison ingots

would appear to be due more to the chemical composition and especially to the nickel and chromium content of this Mayari steel than to any factor traceable to manufacture, which in the case of the comparison ingots is seen to divide them sharply into three groups of very distinct physical characteristics—each a fact which fact the drop test is unable to reveal.

METALLOGRAPHIC TESTS

A sulphur print, light etching, and two photomicrographs at 100 diameters were taken of each test piece, examples of which are given in Figs. 3, 5, 6, 7 and 8 (micrographs are here represented at 35 diameters).

Photomicrograph A was taken at upper part of web, B corresponds approximately with "O" position of Fig. 3. These tests were also made on sections of the 5-ft. pieces of the M-x, M-a and H-a rails to accompany the determinations of discard for chemical segregation.

The metallographic tests throw additional light on the question of segregation and soundness, and especially with reference to the presence of slag inclusions, streaks and seams. They also furnish evidence as to the uniformity of the operations in the rolling mill; although there appears also to be a distribution of structure for each ingot characteristic of its manufacturing processes preceding the rolling.

³See pp. 969 and 974.

FIG. 8. RAIL H16-B

Homogeneous rail from bottom of same ingot yielding rail H16-A (Fig. 7).

A—Moderately fine grained structure, with a thick ferrite network.

B—Average fine grained structure, pearlite with a ferrite network.

The smoothness and evenness of tone of the sulphur prints of all rail sections from the Hadfield sink-head ingots, which are characteristic of the lot (Figs. 7 and 8), even from sections in the drop-test portion near the top of the ingot, is in striking contrast to the markedly irregular sulphur prints from comparison rails (Fig. 3)", except for a few below the center of some of these ingots. Most of the rails from the Maryland ingots show very pronounced irregularities in terms of the sulphur prints, some of them from bottom of ingot showing well-defined pipes (Figs. 6 and 7).

As to the microstructure of the steel, here again the sink-head ingots show much the greater uniformity. This is especially true for the upper portions of the ingot, where differences would be expected.

The rails from the comparison ingots below the segregated area have about the same structural characteristics as the sink-head, except that for many of them the ferrite network is less pronounced and in some cases almost absent. The rolling and finishing temperatures of the ingots were not widely different and do not appear to play any considerable rôle in determining differences of structure. The manganese content, usually somewhat higher in the Hadfield ingots, apparently acts to accentuate the sharp, definite boundaries of ferrite surrounding the pearlite grains.

Sink-Head Ingot H37. Sink-head ingot H37 was cut in halves at Sheffield and Sir Robert Hadfield reports: "The whole of this ingot could be worked into rails after cutting off 10 per cent discard. The ingot is perfectly sound and represents the average quality of the whole of the thirty-six ingots sent to be rolled into rails."

"The capacity of the sink-head cavity of this ingot

was 8,125 c.c., and the percentage of settling by weight in pounds—that is, of the total weight of the ingot was 2.58 per cent. The weight of the material which passed from the head portion into the ingot itself was about 130 lb. This ingot was selected because it showed the lowest cavity percentage—i.e., 2.58 per cent."

Sink-Head Ingot H32. Sink-head ingot H32 was cut in halves at the Bureau of Standards. A photograph of a sulphur print of longitudinal half section of the ingot is shown in Fig. 9. Figs. 10 to 13 show the location of drill holes for chemical analyses of this ingot, as well as the results of the analyses. Only

carbon, phosphorus, silicon and sulphur surveys were made, as the rail analyses indicated that there was no appreciable segregation of manganese in similar ingots. The results indicate that with about 9 per cent discard, steel free from piping and appreciable segregation is obtained.

Carbon showed a high degree of segregation (0.68 to 1.13 per cent), but it will be noted that this is confined to extreme upper portion of the ingot. The high carbon content at this point is probably due to the fact that the steel in the top part of the ingot absorbed carbon from the charcoal used to keep the ingot hot on its upper surface while cooling.

Phosphorus, silicon, sulphur and manganese are remarkably uniform in this sink-head type of ingot.

Split Blooms. The top blooms from ingots H5 and M10 were split longitudinally at the Bureau of Standards and one half of each used for sulphur prints (Fig. 14) and the other half of each for a chemical survey of carbon, phosphorus, silicon and sulphur segregation.

As in the case of the sulphur prints from the rails, the sulphur print from the bloom of the sink-head ingot is of even tone, while the comparison bloom shows decided irregularities. In addition, the latter bloom has enclosed piping about 12 per cent below the top. The chemical survey shows the Hadfield bloom to be very uniform. The maximum carbon is 0.90 per cent, and this is only 4 per cent from the top of the ingot. The comparison bloom, according to chemical analyses, is also quite uniform except for the sulphur content, which is very irregular. This element attains a maximum of 0.166 per cent at 12 per cent from the top, while it is as high as 0.12 per cent at 21 per cent from the top.

A special sink-head ingot, of the same dimensions and type as the other sink-head ingots but containing chromium and nickel, was rolled into rails so as to permit more accurate comparison with the ingots cast in the ordinary manner. The latter naturally contains small amounts of nickel and chromium from the Mayari ore, from which the product was made.

The mechanical and chemical properties of the five

rails from this special ingot (H38) are given in Table XIV. It will be observed that the yield point (70,791 lb. per sq.in.), the ultimate tensile strength (143,025 lb. per sq. in.) and the Brinell hardness (292) are greater, while the elongation (11.3 per cent) and reduction of area (19.06 per cent) are less than those of the average sink-head ingot. Under the drop test the rails from this ingot behave similarly to the comparison ingots.

From the standpoint of composition the steel from this ingot differs from that of the average sink-head ingot in that it is of higher carbon (0.73 per cent) and lower phosphorus (0.016 per cent) and sulphur (0.018 per

cent); also in that it contains small amounts of nickel (0.19 per cent) and chromium (0.11 per cent).

It was necessary to discard 17.6 per cent of this ingot because of pipe, as against 9.1 per cent for the average sink-head ingot.

Service of Rails From This Investigation. The Pennsylvania Railroad, through A. W. Gibbs, reports as follows on the service of the rails from the earlier investigation and from the present one:

"In January, 1915, the Maryland Steel Co. shipped free for test five No. 1, 33-ft. P. S. 100-lb. open-hearth steel rails rolled from ingots furnished by Sir Robert Hadfield to the Bureau of Standards. These rails were laid in the eastward freight track on Horseshoe Curve, Jan. 20, 1915, and were removed on May 15, 1915. The

*Hadfield and Burgess, *loc. cit.*

Longer piece, top bloom from M10. Shorter piece, top bloom from H5.

average abrasion of the Hadfield rails was 1.16 sq.in. and that of the ordinary rail 0.78 sq.in. None of these rails failed.

"In September, 1915, the Maryland Steel Co. rolled forty-six No. 1 and sixty-one No. 2 P. S. 100-lb. rails (0.33 track-miles) from imported Hadfield sink-head ingots and at the same time rolled fifty-three No. 1 and four No. 2 P. S. 100-lb. rails (0.18 track-miles) from its own ingots for comparison. The forty-six No. 1 Hadfield and fifty-three No. 1 Maryland Special rails were laid on Nov. 26, 1915, in the eastward passenger and freight track on the 5 deg. 30 min. curves between Spruce Creek and Union Furnace, Middle Division, and removed on Oct. 23, 1916. The sixty-one No. 2 Hadfield and four No. 2 Maryland Special rails were laid on a 2 deg. curve in the eastward low-grade track, Philadelphia Division, west of M. P. 69, and are still in track. The average abrasion of the No. 1 Hadfield rails was 0.42 sq.in.; that of the Maryland Special rails 0.37. The rail on low grade was still in track on Oct. 31, 1919; abrasion was then 16.1 per cent for Hadfield and 9.7 per cent for Maryland Special.

"There have been no failures of Hadfield rails or of the Maryland Specials.

"There is evidently no economy in the Hadfield process as regards wear, and it would require a much more extended trial to determine the relative freedom from failure."

The Maryland rails may owe their less abrasion to their content of nickel and chromium. It would appear to be unfair to draw any general conclusions as to performance in service from so few rails as this investigation furnished, although it would not be expected that the Hadfield type of sink-head ingots would furnish any rails showing structural defects.

The service results, showing no failures to date, in the few rails of this investigation cannot be considered conclusive one way or another.

It would be of the greatest practical importance in tracing statistically the origin of rail failures, if, in the reports to the rail committee of the American Railroad Engineering Association, they be grouped with reference to their position in the ingot, and in addition the steel manufacturing process be reported, at least briefly, by such notations as raising steel capped with plates; quiet steel deoxidized with x ounces of aluminum per ton; etc. If then it be found that for a given kind of steel there is a greater or less tendency for certain types of failure to predominate or to exist in certain definite regions in the ingot, corrections could be made intelligently in the manufacturing process.

The present investigation indicates very strongly that one should expect the four types of steel and two types of ingot examined, in view of the sharply differing characteristics, to behave differently in service.

The results obtained indicate a decided superiority of the sink-head ingots over the comparison ingots as

FIG. 15. CARBON AND SULPHUR SURVEY FROM TOP BLOOM H5

made of three grades of steel (Tables XI and XII)", although the sink-head ingots suffered from the disadvantage of having gone cold before rolling. The Hadfield type of ingot required a total discard of only 18.4 per cent on the average (13 per cent top discard to eliminate piping and segregation above 12 per cent), while the average ingot of the ordinary type for rails require a total discard of 43.9 per cent (26 per cent top discard), with great variations dependent upon the furnace and ingot practices. The comparison ingots

FIG. 16. CARBON AND SULPHUR SURVEY FROM TOP BLOOM H10

from heat M1 to M5 of non-deoxidized rising steel, chilled on top of ingot by cast-iron caps, required excessive discard to eliminate positive segregation at the top and negative segregation at the bottom of the ingot, the latter often accompanied by dangerous pipes.

The second heat (ingots M6 to M10) made of rising steel deoxidized with aluminum in the molds and the ingot tops of which were cooled with water, required the least total discard of the three heats. It was more subject to piping and less to segregation than the first heat of ingots made in the usual manner.

The third heat (ingots M11 to M15), made of quiet or "killed" steel, was not chilled on top with water or caps and was deoxidized with aluminum in the molds. The ingots of this heat required an intermediate amount of total discard when compared to the first and second heats; this heat was the only one for which a greater top discard was required to eliminate piping than to eliminate segregation above 12 per cent. One of the ingots of this third heat contained a small pipe at the bottom and all the rails from the middle and bottom of the ingots showed high negative segregation.

The distribution of physical properties throughout the length of each ingot is characteristic not only of the type of the ingot and the casting practice but also of the state of the steel when cast.

It has been established in the foregoing that after removal of the top discard of 13 per cent, the Hadfield type of sink-head ingot is free from piping and undue segregation. The ordinary type of ingot, cast small end up without sink-head as is usual for rail ingots, requires an average top discard of 26 per cent and the remainder of the ingot is liable to contain enclosed piping and excessive segregation. Defective rails, from the middle and bottom portion of the ingot, are not certainly detected by means of existing rail specifications, and as a result of this uncertainty rails containing pipes or excessive segregation may get into service with disastrous results.

The surface condition of the rails from the sink-head ingots was not as good for the ordinary ingots, but this is not considered an essential characteristic of rails from such ingots.

The markedly differing characteristics of the three heats of Maryland ingots leads one to raise the question whether or not it might be advisable to specify, at least in some degree, the methods of steel manufacture or of ingot practice for rails and similar products on which the safety of the traveling public depends.

While it is not claimed that the use of the sink-head process for the manufacture of ingots will solve all rail problems, it is maintained that its adoption would be a step in the right direction in view of the present heavy casualties and property losses on American railroads. The necessary changes in mill operations, it is believed could be made without too great difficulties.

Tanks and Pipe Lines as Causes of Accidents*

A Study of the Hazards Involved in the Use of Storage Tanks and Pipe Line Distributing Systems in Chemical Plants — Safe Methods for the Construction, Cleaning and Repairing of Underground and Overhead Tanks and Pipe Lines

BY HOMER A. HOFFMAN†

PIPE lines and tanks are an important factor in the distribution and storage of liquids in a chemical factory and not infrequently we hear of an accident due to a break in the line, the overflowing of a tank, of persons becoming unconscious while in a tank, and even explosions as the result of directing a line into a tank other than the one intended. Although this is but one of the hazards of the chemical industry, it is one to which considerable attention may be given.

Our first consideration is the liquid to be handled, what are its reactions, its specific gravity and viscosity. In the selection of pipes and tanks it must be known in what way they will be affected by the liquid handled, what will be the probable life of the pipe or tank and will it in any way change the structure or give off impurities that will affect the liquid.

MATERIALS OF CONSTRUCTION

The field to select from is large and various, so that generally a choice can be made to fit the case. For instance, cast iron does very well for sulphuric, but not for tannins, which are best handled in copper- or brass-lined tanks and pipes. A few of the materials may be enumerated, such as stoneware, earthenware, monel metal, which satisfactorily resists acids and alkalis, aluminum for acetic acid, glass-coated or enameled cast iron, hard rubber and wood, all of which are used to meet certain conditions. The choice of woods are cypress, redwood and long-leaved pine.

For high-pressure pipe where the liquid necessitates costly material, cast iron or pipe of sufficient strength and lined with particular material is used. Connections on all high-pressure lines must be flanged, and valves are to be of a reinforced type. It will be found advantageous to use replaceable seats in such valves.

DISCUSSION LIMITED TO STORAGE TANKS AND DISTRIBUTION PIPING

Under location, it may be well to classify tanks for storage and piping for distribution. No attempt will be made to discuss the types engaged in processes.

Tanks used for the storage of flammable liquids should be placed so as to conform to the requirements of the National Fire Protection Association or other similar body. As these come under another subject, "Fire Explosions, etc.," they will not be given here. For non-flammable chemicals the tanks acting as distribution centers may be placed above ground or overhead and under ground.

CONSTRUCTION OF UNDERGROUND TANKS

Underground tanks may be set in vertically or horizontally, the latter being preferable for those of large

capacity. A well or pit of concrete should act as a receptacle, the space between the pit walls and tank should be wide enough to allow the passage of a man at any point and the tank should be mounted about 15 in. above the pit bottom. This will allow for an easy inspection and room for workmen making repairs, and will provide proper ventilation about the tank. If the tank is in too close quarters the painting of it is often overlooked and its life will not be as long as expected.

The pit will withstand the action of fumes and acid far better if lined with asphalt, tar or one of the like preparations on the market. The latter as a rule contains a binder of asbestos or other material which prevents in cracking or scaling off. A stationary ladder should be at the pit opening so a person may emerge without delay. When a person is working in the pit a sign to that effect should be hung outside, or, better still, a man should be stationed above the pit.

Gratings are not suitable pit covers, as they allow water and dirt to accumulate in the pit, but if they are used, drainage should be provided for. Sliding covers or sectional lids are generally used for the purpose.

With a tank in a pit of this type a leak can easily be located and in case of a burst or overflow the contents can be recovered and repairs can be made without removing the tank. Tanks placed so should not exceed 10,000 gal. capacity and should be at least 2 ft. below the ground level or floor surface. All gages should be placed where they can be clearly read, and all control valves, cocks, etc., should be fitted with long stems that can be turned without entering the pit and have on them locks or warning signs if any danger exists or they are likely to be tampered with. Vent pipes should end in a receptacle for that purpose.

DISTRIBUTION FROM UNDERGROUND TANKS

Distribution from underground tanks necessitates pumps or compressed air, the latter being quite satisfactory for a good many liquids. Any difficulties in distribution are outweighed by the fact that there is no drip, splash or spray to contend with, material would not be lost in case of a burst, valves are above the tank, the tank is not easily reached by fire and in plants where space is limited it is out of the way.

LOCATION AND CONSTRUCTION OF OVERHEAD TANKS

Overhead tanks present more problems. The location is an important consideration. If placed over passageways, as is sometimes done, a drip pan of sufficient size, with a drain to a sewer or emergency tank, must be provided to carry off any liquid from a leak, overflow or burst. When placed in or on a building, it must be known that the floor, roof or building will not be overloaded when the tank is full.

*Delivered before the Chemical Section at the Ninth Annual Safety Congress of the National Safety Council, Milwaukee, Sept. 30, 1920.

†Safety Engineer, Monsanto Chemical Works, St. Louis, Mo.

Wood is used to a large extent for overhead tanks, and as the woods previously mentioned will resist the action of sulphuric and acetic acids of 20 deg. B \acute{e} ., many of them, mostly of the open type, are found in chemical works. The failure of wooden tanks is often caused by the corrosion of flat hoops, the inner side of which cannot be seen and any defects noted. It is advisable therefore to use only round hoops, which can be gone over from time to time. Wooden tanks should not be allowed to dry out, but if such is the case the hoops may be tightened before being put into use again.

Dry rot is another cause of failures, so periodical inspections should be made. There must be as small a surface as possible in contact with other materials.

Pressure tanks should be tested over pressure before being put into use. Thus a tank car of liquid chlorine would be subjected to a pressure of about 300 lb. per sq.in. Such a tank will receive jolts, so it must be heavily insulated and the dome fittings incased in a hood. Switchings and siding from which such tanks are being loaded or unloaded should have a warning or lock on the switch.

In the case of all aboveground or overhead tanks a hoseline with a stream sufficient to drown a burst, and an emergency box containing gloves, goggles, safe clothing, etc., should be kept in the vicinity.

A runway or platform should be built over the tops of closed tanks so that valves and cocks can be reached from above or from one side. The chief advantage of the overhead tank is that distribution from it is by gravity.

SAFE METHODS FOR CLEANING AND REPAIRING TANKS

Care in cleaning and repairing tanks is very important, and rules governing such operations should be strictly enforced. The importance of this may be illustrated by an occurrence at our plant which took place before the safety idea was recognized. The work on the particular tank was a welding job and before consulting the superintendent or chemist to ascertain if the tank had been properly ventilated, the welder injected his torch into the tank, causing an explosion which resulted in his death and injury to his helper, who had expected something of the sort and was making a getaway.

On another occasion a foreigner who was employed as a leadburner was found doing a job on a tank that had not been inspected. When asked how he knew it was safe to start, he replied: "He is all right. I try him first with my torch, he no blow up."

It is well to have steady crews to do such work as cleaning and repairing tanks. The accepted method of cleaning tank cars may well be applied to all other large closed tanks. The work of cleaning such tanks should be under the direction of a superintendent and as nearly as possible accomplished from the outside. This can be accomplished by removing the cleaning blank and opening all drains, after which a 2½-in. hose fitted with a curved 2-in. pipe which can direct a stream to any part of the car is used for washing. If the pressure is not strong enough to remove sediment or scale, a hoe fitted with a long flexible handle may be used to good advantage. If there is no bottom outlet, the tank should be filled enough to hold all the sediment in suspension when agitated, so that it may be pumped or siphoned out.

In cases where a workman must enter a tank it should be run full of water to exclude all gases, or a jet of

fresh air run in for a sufficient length of time. A workman entering a tank must be supplied with an approved type of respirator and protective clothing, and if the entrance is through a manhole, he must wear a belt with slings under the arms attached to a flexible cable held at the other end by a man on the outside of the tank. A jet of fresh air from a compressor or some reliable source should be run into the tank as long as there is a man inside.

If an open light or flame is used inside of the tank, we use a helmet which has a hose supplying air from outside the tank or one with a compressed air tank fitted to the helmet, which supply will last for half an hour. Proper supervision is absolutely necessary.

UNDERGROUND PIPE LINES

The same classification, overhead and underground, may be applied to pipe lines. Condition of climate enters as a factor, so that underground lines are preferable in colder climates when not housed or in heated buildings. For outside use where a number of lines are run parallel they should be set below the frost line in half round tile and cover, these acting as a conduit, with a break at intervals to serve as a drain in case of a leak or break. The tile cover not only prevents seepage but can easily be removed for making new installations or repairs.

Pipes, when set in this manner and given a coat of resisting paint, will last for a long while without showing any signs of external corrosion. An exhaust steam line may be run through the conduit to maintain an even temperature in winter months. For heavy pipe or pipe of large diameter such installation is costly and unnecessary.

With underground lines a burst can do little or no damage, there are no drips to contend with, all valves can be reached from above, the tripping hazard is eliminated, no installation is required, there is no freezing in the lines and no danger from falling material when the installation is made.

All valves, cutoffs, cocks, etc., must be clearly marked and open ends tagged to show what is being handled in the line. When compression is used to force the liquid through the lines, all connections should be flanged and the line tested before being put into use.

OVERHEAD PIPE LINES

Overhead lines present quite a few hazards. In routing the lines care must be taken to see that those to contain toluene, benzene, alcohol, etc., are not run above or too near to open flames, boilers and switches, as a drip may become ignited.

Where it is required that acid, lye or other such lines cross passageways, they should be jacketed to prevent a drip or spray from falling on anyone beneath. The hangers supporting pipe should be strong enough to support the weight of a man in addition to the working load, as invariably you will find some person who will lean a ladder against, or stand on a pipe.

All overhead lines should be marked in some way to indicate their contents. The most desirable method is that of painting the lines of different colors, but where this cannot be carried out, all cocks, valves and lines should be marked in some way, and at open ends warning signs should be placed, stating what precaution should be taken or protection worn when handling the contents.

Difficulty sometimes arises due to an accumulation of sludge or the tendency of a liquid to crystallize in the pipe. The latter can in most cases be prevented by using a small steam coil about the pipe and covering with asbestos. Overlooking such a precaution was the cause of an accident at our plant. A length of 1½-in. steel pipe was carrying hot material which crystallized near the open end. In thawing out the pipe, the man used a blow torch, starting at the open end to allow the material to run out as it thawed, which it partly did. Some of it recrystallized, closing the pipe and building up pressure where the torch was being applied. This caused the pipe to blow out along the seam, driving the hot material with such force that it penetrated the man's clothing, burning his arms and chest.

STEADY CREW SHOULD HANDLE INSPECTION AND REPAIR WORK

A periodical inspection should be made of all lines and any faulty valves, leaking connections or corroded pipe be replaced and all lines no longer in use removed. Discarded lines should be allowed to drain, or, better still, be washed out, forcing water or air through them. Too often temporary lines are allowed to remain after having served their purpose. Work on lines should be done from a scaffold built on a level with the line, by persons wearing the proper safe clothing and goggles. Where a connection is to be broken, it should be covered with a shield or covered with a reasonable amount of sacking or rags to absorb drips and a warning sign should be hung below. In all cases the pipe should be supported so that it can be lowered to the ground and not left to fall.

It is very important to have a steady crew to do this work, men who know the rules and observe them, because it is through errors on their part that they or others are injured.

An Application of Super-Centrifugal Force

BY EUGENE E. AYRES, JR.

THREE years ago the commercial centrifuge was unknown to the refiner of vegetable oils. Today the centrifuge is recovering about 225,000 lb. per day of edible oils. Each pound of edible oil recovered means the loss of only about one-half a pound of crude soap material. Each pound of oil recovered means from 6c. to 10c. net profit. For 1920 the collective profit to the refiners in the United States will amount to about \$4,000,000.

The profitable quality of a technical process is not always a correct index of its value as an element of scientific progress, but this case is interesting in that an old familiar principle only modernly understood has accomplished what every refiner has wished to accomplish since the first kettle of cottonseed oil was agitated with lye.

This description is intended not for the vegetable oil specialist, who is already familiar with the process, but for the industrial chemist who may be confronted with similar problems.

An economist would express the refining problem as follows:

The oil expressed from cotton seed is crude oil, in the sense that it is unfit for food products or for the manu-

facture of fine soap. Crude cottonseed oil is evaluated not on the basis of its value as crude but on the basis of the yield and quality of refined oil that may be obtained from the crude by acceptable refining methods. As for quality, the refined oil must have pleasant taste and odor or the absence of taste and odor, and a properly pale yellow color.

The refining is in three steps: a caustic soda treatment to remove fatty acids and allied impurities, bleaching with fullers earth, and deodorization with steam, losses from these operations being in the order given. Losses from the caustic soda treatment are appreciable always and sometimes incredibly high. Research has not disclosed a suitable substitute for the caustic soda treatment. Other alkalis or the use of chemical substances (with few exceptions) in conjunction with caustic soda will produce oils that may not be properly deodorized and bleached.

SOAPSTOCK

The refiner's chief problem has been to secure a higher yield of refined oil without impairing the quality.

The byproduct from the refining is a mixture of soap, oil and impurities. This is called soapstock. The soapstock has a market value as a base for soap manufacture, but the value of soapstock (on the basis of fatty acid content) is from 6c. to 10c. less than the value of refined oil. The obvious thing to do is to conduct the refining in such a manner as to leave as little oil as possible in the byproduct soapstock. Failing this, the oil in the soapstock should be recovered as such.

OIL IN SOAPSTOCK

The practical refiner would narrow the problem as follows:

Suppose a crude oil is composed of 97.5 per cent neutral oil and 2.5 per cent of free fatty acid and associated impurities. To remove the free fatty acid and impurities it is necessary to use an excess of caustic soda. The amount of excess reagent is the minimum that will yield a proper quality of refined oil. After separating the crude soap thus formed, from 100 lb. of crude oil 92.5 lb. of neutral refined oil will be normally recovered. Five pounds of oil that was present in the crude has been lost.

The loss may be fairly distributed between actual saponification by the excess alkali and mechanical association with the byproduct soapstock. The saponified oil cannot, of course, be reclaimed, though refining modifications have been suggested by which the extent of saponification of neutral oil may be reduced. But the oil in the soapstock (about 2.5 lb. in this case) should yield to some recovery procedure.

NATURE OF MECHANICAL LOSS

From a chemist's viewpoint, the mechanical loss of oil occurs in the following manner:

When a volume of rancid oil is agitated with a smaller volume of caustic soda solution, a complex emulsion is produced. In this emulsion, oil is continuous. The suspended globules are not globules of soap water, but are globules of a secondary emulsion. This secondary emulsion is composed of continuous soap-water with very small globules of oil suspended. The oil in the refining kettle immediately after the addition of lye is, therefore, present in two phases—a primary continuous phase and a secondary dispersed phase.

After the break occurs the globules of the secondary

emulsion coalesce and sink, to form a compact layer. This is soapstock. The refined oil that is pumped out of the kettle is the oil that composed the primary continuous phase of the refining emulsion. The oil that was dispersed as globules in the secondary emulsion cannot be pumped out as free oil, for it is stubbornly enmeshed in the soapstock. This oil is enmeshed rather than suspended, because coincident with the "break" is a gelatinization of the strong soap-water, and as the jellied globules coalesce and sink, the tiny dispersed globules of oil are deformed and lie in irregular streaks and strata in the soapstock. The viscosity of the jel is too great to allow interfacial surface tension to act.

The principal emulsion problem of the cottonseed oil technologist has been naturally with reference to the refining emulsion to insure a proper agglomeration and settling of the soapstock, and to secure conditions that will leave a minimum percentage of the oil as a secondary dispersed phase. Investigation of this point is difficult, because modifications in refining technique involve so many limiting factors, such as, for instance, color and taste.

The recovery of oil from soapstock, on the other hand, is not greatly complicated by questions of oil quality, for the reasons that the recovered oil can be so readily re-refined with caustic soda and the quantity of recovered oil is small compared with the output of the refinery. Such a recovery is a problem in subsidence.

Physically, soapstock is rather a nondescript mass of soap, water, oil, solids, salts and organic impurities. Although a little free oil will usually settle out of hot soapstock, it is not possible to separate even a trace of free oil when a hot soapstock is pumped through a most powerful centrifuge. This is easily accounted for by the fact that the recoverable oil is in an extremely unstable condition. The gelatinization of the soap solution while deforming the oil globules also causes considerable agglomeration of oil into strata, but if the viscous mixture is thoroughly agitated, the oil is again dispersed. With such an unstable condition, recovery is possible only when the mass can be undisturbed.

When soapstock is diluted with water to the point where it is no longer gelatinous it may be described as follows:

The continuous phase is water with a trace of inorganic matter dissolved and certain organic matters in colloidal dispersion.

Under a microscope of highest power, the continuous water phase of the soapstock is usually transparent, with a yellow color. In bulk the aqueous phase, when completely freed from oil (by filtration, for instance) is dark brown in color, but transparent, without the faintest trace of opalescence. Under the microscope the oil globules are without color and vary in size from 0.02 mm. down to 0.002 mm., or even smaller. When not prevented by viscosity, the smaller particles exhibit decided Brownian movement.

USE OF CENTRIFUGAL FORCE

Centrifugal machines may be divided into two classes: (1) Those which induce filtration, such as the hydro-extractor; (2) those which induce subsidence. The latter type is applicable to emulsions.

Centrifugal force (like gravity) has two functions--to move the globules down or up, depending upon relative specific gravities, and to cause adjacent globules to coalesce. Centrifugal force has been successfully utilized in the past for the separation of emulsions that

yield both to subsidence and to coalescence. With one exception, emulsions whose globules will not coalesce under centrifugal force have never been resolved centrifugally on a commercial scale. The one exception is milk, oldest and best-known example of centrifugal separation. The cream separator, however, has always been a product of purely empirical design. The more modern centrifugals, adapted, for example, to the separation of water from petroleum, are designed with full scientific understanding of the emulsions for which they are intended.

The cream separator is a practical success only for milk. The subsidence-coalescence centrifugals are not successful with emulsions wherein coalescence will not take place. It has been necessary, therefore, to determine the fundamentals of the class of emulsions of which milk is a special case. This difficulty offers the best explanation of the fact that dilute soapstock emulsions were not satisfactorily centrifuged until recently.

CENTRIFUGAL PROCEDURE IN OIL REFINERIES

The soapstock must be diluted until it is no longer gelatinous. The thin emulsion is subjected to centrifugal force for a sufficient period to move to the surface all oil globules that do not exhibit Brownian movement. The emulsion is thus divided into two new emulsions, one saturated with oil, the other containing only the smallest globules. It is customary to refer to the one as the "light" emulsion, while the other has so few emulsion characteristics that it is termed the "heavy effluent."

The light emulsion on microscopical examination is found to possess a structure similar to that of the diluted soapstock, except that (1) the oil globules are nearly uniform in size, averaging 0.008 mm. in diameter, and (2) the oil globules are packed together very closely, touching each other in all directions.

The heavy effluent from cottonseed oil soapstock consists microscopically of a clear yellow phase containing a few scattered spherical oil globules averaging 0.002 mm. in diameter.

To obtain continuous oil from the light emulsion it is convenient to add salt water and recentrifuge. The salt wholly or partly precipitates the soap from solution and in this way tends to reverse the form of the emulsion—to make oil continuous and water globularly suspended. Emulsions of this type are easily separated by centrifugal force. Preparatory to recentrifuging, other chemical methods of breaking down emulsion stability are satisfactory, but salt is economical and efficient.

Under correct operating conditions, the centrifugal process appears to recover about 60 per cent of the neutral oil present in the soapstock. Yields have been reported as high as 78 per cent and as low as 40 per cent.

It is not to be supposed that any plant now in operation is operating at maximum efficiency. The soapstocks produced at the various refineries are different in many respects. For example, in one refinery it was found that the centrifugal recovery yields were very low because of the fact that the water used for the dilution of the soapstock had been softened. Soft water is not as good as hard water when emulsion stability is to be reduced. Maximum efficiency will come, of course, only as the conditions at each recovery plant are more and more thoroughly understood, and when suitable operating modifications are adopted.

Philadelphia, Pa.

The Separation of Mineral Matter From Natural Flake Graphite

BY W. C. RATLIFF AND JOSEPH D. DAVIS

American flake graphites, as they are put on the market, contain rather large percentages of ash. The ash content of Alabama graphite, for sample, ranges from 9 to 15 per cent, and the figures for Pennsylvania graphite are about the same. The dust or fines resulting from the refining or grading of the flake are much higher in ash. No. 1 dust from Alabama flake graphite contains about 55 per cent ash, while the ash content of No. 2 dust will run as high as 70 per cent.

The Bureau of Mines has been conducting investigations looking toward the better utilization of American graphites, and this paper represents a part of the investigation.

There may be some question as to the economy of further purification of the coarser flakes, particularly when they are intended for use in crucible making, but the dusts as they come from the refinery are not readily marketable, and it is believed that if they were free from mineral matter they would be in demand for such purposes as the manufacture of stove polishes, graphite paints and lubricants, and particularly for the manufacture of graphite electrodes. It was for the purpose of developing a method for the purification of dusts that the experimental work which follows was undertaken.

METHOD ADOPTED FOR PURIFICATION

The method used in this experimental work was that devised by Lieutenant Walter E. Trent primarily for the purpose of removing mineral matter from coal. The method is essentially as follows:

The coal to be treated is finely pulverized and thoroughly wetted with water, the weight of water added being at least twice the weight of the coal. Enough oil is then added to saturate the coal (usually about 1 part oil to 2 parts coal), and the mixture is thoroughly agitated with some efficient type of mechanical agitator. The effect of the agitation is to cause the coal and oil to be agglomerate, leaving the mineral matter suspended in the water, with which it can be poured off from the coal-oil mixture. By repeatedly agitating the coal-oil mixture with fresh portions of water and pouring off the wash water, a large part of the extraneous mineral matter can be removed. Most of the water held mechanically by the pasty mass of oil and coal can now be removed by squeezing as butter is worked.

PRELIMINARY EXPERIMENTAL WORK

A 100-g. sample of Alabama flake graphite was thoroughly agitated in a small hand churn with 100 c.c. of topped crude oil of paraffine base and 0.87 specific gravity, and about 200 c.c. of water. The graphite and oil agglomerated with a fairly good separation of the water. The water, however, carried only a small amount of mineral matter from the graphite, and the sample was known to contain over 12 per cent ash.

It was now decided to investigate the effect of fineness of grinding. Accordingly, a fairly large sample of the Alabama flake graphite was ground in water for about eight hours in a ball mill, and then filtered

and dried for one hour at 105 deg. C., to remove all the moisture. On visual inspection, the size of the flakes seemed to have been considerably reduced. On close examination, however, under the microscope, Dr. Reinhardt Thiessen of this bureau found that the area of the flakes had not been greatly reduced, but that they had been reduced in thickness. The thin laminae of which the flakes are made up had been separated, leaving the mineral matter held between the laminae exposed. A 60-g. sample of this ground graphite was agitated with 60 c.c. of topped crude oil and 120 c.c. of water. The water decanted from the agglomerated mass of graphite and oil carried with it quite a large amount of mineral matter resembling clay. Fresh water was added and the mixture was again thoroughly agitated, after which the water was poured off from the graphite and oil, containing apparently as much sediment as that from the first treatment.

The washing with water was repeated until the water came off clear, six washings being required in all. All the washings were then collected and filtered, and the residue was ignited in a muffle furnace for one hour, after which it was cooled and weighed. The weight of the residue so obtained amounted to 10.16 per cent of the weight of the sample treated. A portion of the graphite-oil mixture was now extracted with benzene to remove the oil, the benzene was driven off and the amount of ash in the residue was determined. It was found to contain 3 per cent ash, whereas the original graphite sample contained 13 per cent ash.

Another test was made wherein only half as much oil was used as in the test just described, but this amount of oil failed to effect good agglomeration. About equal portions of oil and graphite gave the best results. The amount of water required was approximately twice that of the graphite. Further additions of water had no effect on the agglomeration, but aided in keeping the mineral matter in suspension so that it could be more readily removed from the oil and graphite.

COMPARATIVE EFFICIENCY OF DIFFERENT AGGLOMERATING LIQUIDS

Having found that heavy oil gave fairly good results as an agglomerant, it was decided to try the agglomerating effects of lighter and more volatile liquids, the idea being to find a liquid that would do the work as well as the oil and at the same time be more readily recovered by volatilization. No doubt the surface tension and viscosity of the liquid used have an important bearing on its behavior, but these are matters which require more extended study than this paper contemplates. The known requirement of a liquid agglomerant is that it must be immiscible with water. Benzene, toluene and carbon tetrachloride answer this requirement and were selected for comparative test with oil. All these liquids gave good agglomeration when churned up with the graphite and water, but the carbon tetrachloride apparently gave the cleanest separation of the water and agglomerated mass. The comparative washing efficiencies of the liquids were now determined quantitatively.

For the determination, large samples (approximately 2 lb.) of Alabama and Pennsylvania graphites were ground in a ball mill with water for about eight hours. The samples were then dried at 105 deg. C. until all the moisture was removed. Fifty-gram samples of the ground graphites were thoroughly agitated with 50-c.c. portions of the different liquids, about 200 c.c. of water being added in each case.

The agglomerated residues were now washed until the decanted water was clear. This required from five to eight washings with 200 c.c. portions of water. The benzene, toluene and carbon tetrachloride, being readily volatile, were easily driven out of the graphite by heating, and the oil was extracted from the oil-graphite residue with benzene. After thoroughly drying all the samples, duplicate samples of each were weighed out and ashed to constant weight in a muffle furnace at about 800 deg. C. Table I gives the results of the washing tests.

It will be noted that the efficiencies of benzene, toluene and carbon tetrachloride are very nearly the same, whereas that of oil is different and not so good. In the

TABLE I

Per Cent Ash in Alabama and Pennsylvania Graphites Before and After Treatment With Topped Crude Oil or Tetrachloride

Kind of Graphite	Untreated	Treated With			
		Oil	Benzene	Toluene	Carbon Tetrachloride
Alabama	11.68	4.28	5.44	5.41	5.30
Pennsylvania	10.03	6.43	5.54	5.71	5.55

case of the Alabama graphite the amount of mineral matter removed by the lighter liquids averages 72.7 per cent of the total mineral matter contained, while that removed by the oil is 63.3 per cent of the total. In the case of the Pennsylvania graphite, the lighter liquids removed 41.1 per cent of the total mineral matter and the oil removed 35.8 per cent of it. The greater efficiency of the treatments in removing ash from the Alabama graphite may be accounted for by the fact that the Alabama flake was finer than that from Pennsylvania. This is shown in Table III, which gives the size tests on all samples used.

Although the efficiencies of benzene, toluene and carbon tetrachloride are about the same, carbon tetrachloride was used in making further tests, since it gave the best agglomeration and the cleaner cut separation of the agglomerate from water.

EFFECT OF SIZE OF GRAPHITE PARTICLES

Fairly large samples (approximately 100 g.) of the Alabama and Pennsylvania graphites were ground in the ball mills for eight hours and then treated with carbon tetrachloride and washed to free them from suspended mineral matter. The samples were then dried at 105 deg. C. to remove all the carbon tetrachloride and moisture. Small samples of the residues were reserved for determination of ash and the remainders were again ground wet in the ball mills, this time for twelve hours. They were then treated with carbon tetrachloride and separated mineral matter was removed by

TABLE II

Per Cent Ash Remaining in Alabama and Pennsylvania Graphites After Eight and Twenty Hours Grinding, and Treatment With Carbon Tetrachloride

Kind of Graphite	Per Cent Ash	
	Ground 8 Hr.	Ground 20 Hr.
Alabama	3.51	1.56
Pennsylvania	5.65	1.75

washing as before. The resulting agglomerates were now dried and ash determinations were made on the dried final product. The results of the tests, as shown by the ash determinations, are given in Table II.

In order to get the relation between the fineness of the graphites and the amount of ash removed in each case, size tests were made on all samples treated, and the results of the tests are given in Table III.

TABLE III

Results of Size Tests on Alabama and Pennsylvania Graphites

	Alabama Graphite			Pennsylvania Graphite		
	Un-ground	Ground 8 Hr.	Ground 20 Hr.	Un-ground	Ground 8 Hr.	Ground 20 Hr.
in 48 mesh	11.7	9.5	1.5	74.4	80.6	10.3
Through 48, on 100 mesh	82.2	70.0	32.9	25.0	15.4	32.7
Through 100, on 200 mesh	5.2	12.7	31.1	0.1	1.7	28.2
Through 200 mesh	0.9	7.8	43.5	0.5	2.3	28.8

These size tests give only an approximation of the actual sizes of the graphite flakes, since in every case the flakes were somewhat broken up in going through the screens. Particles that should have been retained on the screens passed through before constant weight on the amount retained could be secured. This is true of the unground sample of Pennsylvania graphite, where a smaller quantity was retained on the 48-mesh screen than that retained on the same screen after eight hours' grinding. However, in general, the size tests do show a reduction in size by grinding. Microscopic examination showed that the thickness of the flakes had been greatly reduced, but that the area had not been reduced so much. By picking apart the flakes with a needle, particles of clay could be dislodged from the laminae. The main effect, then, of grinding the flake graphite was to break apart the laminae and expose the mineral matter, which was then easily removed by treatment with carbon tetrachloride with subsequent washing.

TREATMENT OF OTHER GRAPHITE SAMPLES

A sample of Alabama flake dust, containing 37.63 per cent ash and of such fineness that 52 per cent of it passed 200 mesh and the remainder passed 100 mesh, was treated with carbon tetrachloride and washed in the usual manner. After treatment, the ash remaining in the graphite amounted to 22.59 per cent. This residue was now ground wet in a ball mill for seven hours, and, after washing, the amount of ash still held by the graphite was 7.87 per cent.

A very finely pulverized sample (100 per cent passed 200 mesh) of amorphous Mexican graphite was treated with carbon tetrachloride and washed free from separated mineral matter in the usual manner. The ash content of the original sample was 15 per cent and the amount remaining after washing was 7.5 per cent. It was shown that the ash content of the sample could be further reduced by grinding, but quantitative reduction tests were not made.

CONCLUSION

From the results of the experimental work just described, the following conclusions may be drawn:

1. Graphite, both flake and amorphous, may be cleaned by agitating with oil and water.

2. Light volatile liquids, benzene, toluene and carbon tetrachloride, are better adapted to the cleaning of graphite than oil. It is probable that this is due mainly to their lower viscosity. It was noted that with the lighter liquids the agglomerates formed were much less viscous and that mineral matter separated with much less agitation than in the cases where heavy oil was used.

3. The extent of the cleaning effected by this method depends indirectly on the fineness of the graphite treated. The value of grinding is not so much due to actual size reduction thereby as to a separation of the mineral matter from inclosing carbon.

Molybdenum During 1917-1919*

BY FRANK L. HESS

THE molybdenite deposits of the United States are legion. This mineral has probably been found, at least in small quantity, in every state in which there are any considerable outcrops of granite. In the Rocky Mountain and other Western States individual occurrences are too numerous to record. Like gold leaf, molybdenite is apt to be spread so thinly and to make so great a show compared with its real bulk that a much exaggerated impression of its quantity is had unless dependence is placed on assays alone. Molybdenite [the sulphide of molybdenum (MoS_2)] and by far the commonest molybdenum mineral is so attractive when seen in the white quartz in which it is commonly found and so deceptive in its appearance of quantity, and so many stories of its great usefulness and value have been current, all with a touch of the mystery connected with supposed secret uses, that many persons have been induced to invest much more labor and money in molybdenum mining enterprises than careful investigation would warrant.

In 1918 the United States retained its lead as the greatest producer of molybdenum by an output of 431 short tons of metal in 2,280 tons of ore and concentrates valued at \$1,253,700.

In 1918 the center of production moved from Arizona to Colorado. The dumps of the old Mammoth gold mine, from which a large part of Arizona's production had come, had yielded their crop of wulfenite, though the mine is still productive; but the great size of the Colorado deposits and the large mills give an output which is far greater than that of any other state.

DISPOSITION OF MOLYBDENUM IN 1917

The Atlantic Metal & Alloys Co., Boonton, N. J.; the Arizona Rare Metals Co., Tucson, Ariz.; the Primos Chemical Co., Primos, Pa.; and the Rose Chemical Co., Los Angeles, Cal., made ferromolybdenum during 1917. The Atlantic Metal & Alloys Co. went out of business during that year, and the Tungsten Products Co., of Boulder, Col., took over its slag on hand and produced ferromolybdenum from it.

So far as is known, except for a small quantity used experimentally and another small quantity used by one firm in tool steels, all the ferromolybdenum made in 1917 was exported, most, if not all, going to France, and most of the concentrates produced in this country that were not reduced to ferromolybdenum were also exported to France. Small quantities were used for the production of molybdic oxide, molybdic acid and ammonium molybdate. The molybdic oxide and molybdic acid were used either to make ammonium molybdate or molybdenum (metal).

CONSUMPTION IN 1918

In 1917 and in the earlier part of 1918 there was a good foreign demand for molybdenum ores and ferromolybdenum, and considerable quantities were used by the Ford Motor Co. and the Carbon Steel Co. in the United States, but the domestic market was very restricted and was supplied during the first part of the year mostly by the Climax Molybdenum Co. and the Primos Chemical Co.

The Ford Motor Co. had a contract to supply crank

shafts and connecting rods for Liberty aircraft engines to the Government, and in these 0.35 to 0.50 per cent of molybdenum was used, with more chromium and nickel. A crank-shaft forging weighed 196 lb. and an extra shaft was shipped with every twenty-five Liberty engines. The yield of forging bars was about 60 per cent per heat in the electric furnace, and about 90 per cent of good shafts were obtained from the bars. The connecting-rod forgings weighed about 62 lb. per engine, and each electric furnace heat also gave about 60 per cent of good forging bars but only about 80 per cent of finished forgings from the bars. About 100 crank shafts was the maximum daily output, with presumably an equal number of connecting rods.

During the summer small plates of similar steel exhibited had shown great resistance to light projectiles, and it was proposed to make all armor for tanks and airplanes of similar steel.

The Government did not itself buy any molybdenum ores for the work, but gave its assistance to the companies which were to make the steel in their efforts to obtain ferromolybdenum quickly and guaranteed their contracts. Before the steel was made the company that had advised the use of molybdenum steel announced that it had obtained better results with steel carrying a very small percentage of zirconium, and the company was told to go ahead with zirconium steel if that would afford the best possible protection. Baddeleyite (zirconium oxide) was therefore ordered from Brazil, but before either steel was actually used the armistice was signed and all contracts were nullified.

MARKET CONDITIONS IN 1919

The reaction in the molybdenum market caused by the cessation of hostilities and the withdrawal of the European demand for molybdenum ores and ferromolybdenum probably reached a maximum during the year 1919.¹ The development of new properties and the production of increased quantities of ore, stimulated by the active demand, more especially during 1917, naturally resulted in overproduction as soon as the war demand ceased. The largest single consumer, the Ministry of Munitions in London, announced early in the year that accumulated stocks in the United Kingdom were large enough to meet all demands for at least eighteen months. Most of the production within the British Empire was under contract at a fixed rate. Arrangements were therefore made to reduce drastically all shipments from outlying points to allow existing stocks to be realized and to permit the world's market to settle down to a normal working condition as soon as possible. The Ministry of Munitions therefore terminated the existing purchasing arrangements and no deliveries of molybdenite loaded on ocean steamers from British overseas ports after April 30, 1919, were to be accepted. The Ministry of Munitions also recommended that empire producers, in their own interests, should take immediate steps to reduce the production of these ores.

The agents of the Federal Government of Australia continued purchasing supplies of tungsten and molybdenum ores at the scheduled prices to Dec. 31, under the contracts previously made by the Commonwealth Government with the Imperial Government. During the negotiations the Imperial Government advised the

Commonwealth Government that the estimated stock of tungsten and molybdenum minerals in Great Britain at the end of 1919 would be sufficient to meet the requirements of the home and export trade of the United Kingdom for at least two years. It was expected that these stocks would have to be realized by the Imperial Government at prices below the fixed standard at which they had been purchased.

Overproduction, beyond the ability of the market to absorb, quickly resulted either in the accumulation of stocks at some of the mines or in the cessation of mining. Production had stopped at nearly all the mines early in the year, and some new properties that were ready to produce concentrates found themselves without a market.

COLORADO DEPOSITS

The greatest single feature of 1918 in the mining of molybdenum was the building of expensive and elaborate mills by the Climax Molybdenum Co. and the Molybdenum Products Corporation and the development of their holdings on the great deposit on the west side of Bartlett Mountain, at Climax, Summit County, fifteen miles north of Leadville, Col. The Climax Molybdenum Co. had its mill sufficiently finished to carry on experimental work in the latter part of February and in March. In April the mill was running regularly.*

The Molybdenum Products Corporation has a patented claim 150 by 1,500 ft. located on the same ore body, and had the ore on at least three sides of its claim. It got to work later than the Climax Molybdenum Co. and was not so fortunate in disposing of its product, so that it operated only a short time. So far as it is already explored the deposit can probably supply 100,000 tons of elemental molybdenum. Both companies are ready for operation at any time that a demand sufficient to warrant operation arises.

WORLD'S PRODUCTION

The United States and Canada apparently have the largest known molybdenum supplies. It is believed that the United States has the greatest individual deposits and the greatest quantity of available ore, but neither Canadian nor American Government geologists have examined deposits in both countries, and private opinions differ. The United States has for some years been the largest producer of molybdenum ore and is in a position to increase production greatly whenever the market warrants.

The accompanying table shows the world's production of molybdenum contained in ore, so far as the data are

at hand, for the years 1914 to 1918, inclusive. No facts are now known that indicate a greatly different distribution in the near future. It is known that some molybdenite has been produced in Germany and some wulfenite in Austria, but the quantities are unknown.

Legal Notes

BY WELLINGTON GUSTIN

Hair-Line Cracks on Ingot Steel Not Breach of Warranty Against Serious Surface Defects

In the case of the Clark Equipment Co. against the John A. Crowley Co., judgment for the former being recently affirmed in the United States Circuit Court of Appeals, the controversy involved hair-line cracks on the surface of steel ingots, rendering them unfit for gun forgings.

The Crowley company sought to defeat payment for the ingots, claiming the plaintiff had breached its warranty in forging the ingots. The warranty insisted on is found in the order for manufacture given by the Clark company to the Crowley company and in a nearly contemporaneous letter explaining what was wanted. The order was prepared by the buyer and tells the forge company that its acceptance "constitutes a guaranty that all steel furnished [under the order] will be free from all physical defects." The letter charges the forge company that its "responsibility consists" in furnishing steel "free from surface defects and an unusual amount of pipe"; wherefore [wrote the buyer] "please use care; . . . serious surface defects will be cause for rejection of the entire ingot."

Now it was laid down that where the warranty on a sale of goods was contained in the order and letter, both of which were prepared by the buyer, any doubt as to construction of these writings will be resolved against the buyer. The above warranty is one as to quality; the rule applicable being that there must be a substantial compliance, and substantial failure being a breach.

The forge company or seller admitted the existence of "hair-line" cracks on the ingot surface, but averred that it had "chipped out" the same so that the ingot was either "perfect" on delivery, or was made so thereafter, at its expense. There was evidence that such cracks were a necessary result of cooling of metal, and

*See CHEM. & MET. ENG., VOL. 19, p. 654, Nov. 1, 1918.

their removal produced perfection, and also that steel of the composition and ingot size contracted for could not resist without cracking the method of forging adopted by the purchaser. On the other hand, the purchaser gave evidence that "fine cracks" discoverable by "a more or less careful scrutiny" existed before forging, and under "the hammering process . . . they became larger."

The only point properly before the court was whether what the seller called "hair-line cracks," removed by chipping, constituted "serious surface defects." It was held that hair-line cracks chipped out before delivery and serious surface defects are not convertible terms, and the jury having found as a fact that the ingots delivered did conform to the terms of the contract, the judgment for the seller was affirmed.

Plant Must Be Operated Not to Interfere With Health of Neighboring Residents

The rules governing liability for maintaining an industrial plant as a nuisance are laid down in the decision of the Supreme Court of Minnesota in two actions brought by Alice Millett against the Minnesota Crushed Stone Co.

Millett brought suit to recover damages extending over a period of six years from the operation of a quarry, crushing plant and grinding mill near her home. It was claimed that because of noise and jar of blasting, the noise and danger of falling rocks, the noise of steam drills and of a steam shovel, and because of smoke and dust, the plant was a nuisance. On trial the jury found against the company and it appealed.

The Supreme Court stated the rules in effect to be that a land owner who has a deposit of limestone or other product on his land may not quarry as he chooses, but he may be liable for maintaining a nuisance in the operation of a quarry and other incidental industries, even though the odors, noise, dust and the like complained of are ordinary incidents of such a business conducted without negligence; that the rights of inhabitants are superior to the rights of trade, and that, whenever they conflict, the rights of trade must yield, that such a business must be conducted in such a manner as not to offend or interfere materially with the health or ordinary physical comfort of people living in the neighborhood.

Two questions were presented for determination by the Supreme Court: First, whether the home owner was entitled to recover for the diminution of the value of the use of the property. Second, whether recovery for personal discomfort, inconvenience and ill health is an additional element of damage.

Answering the first proposition it was said that a property owner whose property is injured by a nuisance may recover for the property damage sustained. This is generally the diminished rental value, if the property be rented, or the diminished value of the use, if the property be used by the owner (2 Sup. Court, 719). This element of damage is recoverable only by the owner (Jefferson Fertilizer Co. vs. Rich, 62 So., 40).

Answering the second proposition, the court said the rule was now well settled that in an action for damages for maintaining a nuisance recovery may be had for inconvenience, physical discomfort and illness to the occupant of the property resulting from the nuisance. This element of damage is something additional to the element of diminished rental value.

In an action for a private nuisance, affecting injuriously the health and comfort of the occupants of the homestead, the husband and father of the family, if he be the owner, may recover for any discomfort, annoyance or illness suffered by himself or any member of his family resulting from the nuisance. And it is not permitted to each member of the family to maintain separate actions to recover these elements of injury. This rule is laid down to avoid a multiplicity of law suits.

Company Has Right to Replace Old System to Preserve Investments

An attempt to enlarge profits in salt manufacture got the Buckley & Douglas Lumber Co. into the courts through a controversy among its directors. In an earlier case brought by the State of Michigan against it, the company was permitted to manufacture salt as an incident to the manufacture of lumber, and as the salt business was extended of late years, the quantity of logs sawed has diminished.

The increasing manufacture of salt brought about an increasing problem of fuel. Coal burned by the company in plant 1 amounted in 1915 to \$45,435; in 1917, \$86,468; and in 1918, \$153,575. The value of the salt block and equipment in 1910 was about \$225,000, and in 1918 about \$350,000.

In 1918 a contract was entered into with the Manistee Iron Works Co. for the installation in plant 1 of new pans and a new system of applying steam thereto whereby it was claimed the same quantity of salt could be produced by the use of one-fourth the amount of fuel. The purchase price of the new equipment was \$238,650, and the cost of installation would make the total cost thereof about \$300,000.

The complaining directors, who voted against this transaction, brought suit against the companies and majority directors, contending the contract was unlawful, and asked that the court declare said contract *ultra vires* and void, and that defendants be restrained from doing any act under it, holding the individual defendants personally liable.

The questions presented were: First, had the board of directors the power to enter into the contract to replace with the iron company? Second, if they had such power, was the making of such contract a legal fraud upon the rights of the minority stockholders?

The court said the board had the same right as a copartnership or an individual would have to enter into any contract reasonably adapted to further the business of the corporation, if within the powers conferred by its charter. They may generally do whatever an individual, acting intelligently and honestly, would do under similar circumstances.

Plant 1 included a warehouse with a capacity of from 350,000 to 400,000 bbl., five salt wells about 2,000 ft. deep, railroad tracks, docks and shipping facilities, besides apparatus for manufacture of salt. Its total cost has been about \$350,000. The board was found to be justified in preserving this investment in the manner it followed, by replacing worn-out salt-manufacturing apparatus with a new system which allows greater salt production with less fuel. And the directors had the power to contract in good faith to replace worn-out apparatus for its incidental salt manufacturing, and such was not a fraud on minority stockholders. Such was the judgment of the Supreme Court of Michigan.

Notes on Pulp and Paper*

THERE are four general processes of reducing wood to a pulp condition—namely, the ground wood, sulphite, sulphate and soda processes of pulping.

THE GROUND WOOD PROCESS

The ground wood process of pulping is used mainly for the reduction of non-resinous, long-fibered wood, such as spruce and balsam. The barked wood in 2-ft. lengths is ground on a grindstone, the surface of which has been sharpened to produce a cutting action. The yield of pulp is approximately 90 per cent of the weight of the raw wood. The pulp is inferior in quality and is used only to mix with longer- and stronger-fibered stock such as unbleached sulphite pulp—in the manufacture of paper in which permanency is not required, as in news-print, cheap catalog, magazine and certain other papers. It is also used to a large extent in the manufacture of wall board.

THE SULPHITE PROCESS

The sulphite process is used chiefly for the reduction of long-fibered, non-resinous, coniferous woods, such as spruce, balsam and hemlock, giving a yield of less than 45 per cent based on the weight of the original wood used. This pulp can be bleached to a high degree of white and is largely used both unbleached and bleached in the manufacture of books, news-print, wrapping, bond and tissue papers.

THE SULPHATE PROCESS

The sulphate or kraft process of pulping is used for the reduction of any long-fibered wood and yields approximately 45 per cent. This is an alkaline process and can be used for the reduction of both resinous and non-resinous woods, such as the pines, spruces, hemlocks, firs, etc. Kraft pulp is normally not bleached but on account of its strength it is used for the manufacture of kraft wrapping paper and high-test container board.

THE SODA PROCESS

The soda process is restricted in use to the short-fibered deciduous woods, such as aspen, cottonwood, willow, gum woods, etc., yielding less than 45 per cent. The resulting pulp is invariably bleached to a high degree of white, and after admixture with a longer- and stronger-fibered stock, such as spruce sulphite, is used for the manufacture of book, lithograph, envelope papers, etc.

COST OF A PULP AND PAPER MILL

No accurate figures are available as to the cost of a pulp and paper mill, but it is the opinion of the laboratory that under present conditions a balanced pulp and paper mill cannot be erected at a cost of less than \$45,000 or \$50,000 per ton capacity of finished paper per day. It is not feasible, except under abnormal conditions, to erect a pulp plant of less than twenty-five tons capacity, requiring approximately sixty cords of wood a day. Before proceeding with the erection of a pulp and paper mill a competent engineer who has specialized in this field should make a very careful survey of the economic conditions, such as labor, markets, living conditions, cost of fuel and power, as such factors are of decided importance

in determining whether or not the enterprise will be a financial success.

American conditions are deemed unsuitable for plant fiber paper. General investigations have shown that fibers such as sugar cane bagasse, corn stalks and various straws offer the following difficulties in handling:

DIFFICULTIES IN USING PLANT FIBERS

1. Plant stalks, straws, grasses, etc., usually contain a large percentage of pith, giving pulps low in fiber content and requiring high chemical consumption.

2. Material of this type represents seasonal crops, so that facilities must be provided for the storage of a large volume of the stalk in order to permit the paper mill to operate throughout the year. The susceptibility of such material to decay adds greatly to the costs and difficulties of storage.

3. Due to the bulkiness of these materials the digester charge is reduced, thereby reducing the yield and increasing overhead costs proportionately.

Some of these fibers, such as straws, are being pulped at the present time for use in the manufacture of corrugated board and cheaper board products. Pulp of this nature, however, does not compare with a refined pulp such as sulphite or rag stock; it can be used only for special purposes and not in the manufacture of news-print or high-grade paper. Plant fibers of this nature are being reduced commercially in Europe where economic conditions and the scarcity of wood permit their utilization.

AVAILABILITY OF SOUTHERN WOODS

There has been considerable inquiry concerning the suitability of Southern woods for paper manufacture. While these have a good fiber length, on account of their pitch content they cannot be reduced by either the sulphite or the ground wood process to compete commercially with pulp made from Northern coniferous woods, such as spruce, balsam or hemlock.

SOUTHERN PINES

The various species of Southern pines can best be reduced by the sulphate, or kraft, process of pulping, and the resulting pulp utilized for the manufacture of kraft wrapping paper or high-test container board. These pines can also be reduced by the soda process and the resulting pulp utilized in the manufacture of grades of paper in which sulphate pulp is ordinarily used. It is possible that further work will demonstrate the feasibility of pulping these pines by the sulphate process, bleaching the pulp to a satisfactory degree of white and mixing it with short-fibered sulphate or soda pulp made from other Southern woods, such as the gum woods, for the production of magazine, book, envelope or lithograph papers. The yield of pulp by the soda and sulphate processes is less than 45 per cent.

SOUTHERN HARDWOODS

The large stands of hardwoods occurring in the South consist in part of the various species of gum wood, cottonwood, sycamore, basswood, magnolia, willow, etc. All of these woods are short-fibered and, according to laboratory experience, can be most satisfactorily reduced by the soda and sulphate processes of pulping. This pulp after admixture with a longer- and stronger-fibered stock, such as bleached spruce sulphite or pine sulphate pulp, can be used for the production of book, envelope or lithograph paper.

*Abstracts from the Forest Products Laboratory Technical Notes.

Producer Gas-Fired Boiler Installation in France

A Description of the Installation and Operation of a Producer Gas-Fired Boiler Plant at the Montrambert, Loire, Coal Mines, Using Coked Slack and Mine Waste for the Production of the Gas

BY JOHN H. BARTLETT, JR.

ENGINEERS and works' managers are frequently heard to express certain doubts as to the possibility of obtaining complete combustion with gas of very low calorific value without the use of supplementary heat furnished by pre-heating the air destined to support this combustion.

Difficulties in lighting and in maintaining a stable combustion are feared and it is commonly considered to be of prime necessity to provide for an excess of air in order to insure the gas being completely burned. For the most part, these ideas are traceable to the fact that the designs and equipment used have almost always been more or less defective, and it is thought that in this connection a short description of the tests recently made on firing a water tube boiler with lean producer gas at Montrambert (Loire) may be of some interest.

Some readers may be already familiar with the studies and experiments carried on during latter years by the Société des Houillères de Montrambert et de la Béraudière of St. Etienne (France) with the aim of utilizing in the most economical and rational way the slack from its mines and its low-grade coals. In order to pursue these studies this company built a complete test works of 500 kw. capacity which is operating regularly at present, furnishing the power used in the

parts. The coal is first charged into coke ovens, the byproducts being recuperated and the waste heat employed for steam generation; the coke thus formed is next utilized in gas producers and the gas produced is employed in two internal combustion engines for generation of electrical power.

By this method are avoided the difficulties resulting from a direct treatment in producers of a coking coal, rich in viscous tar and which produces continuously, through agglomeration, compact masses of clinker in

FIG. GENERAL VIEW OF PRODUCER INSTALLATION

FIG. 1. THE BUTNER BOILER WITH GAS BURNER INSTALLED

exploitation of the shafts at Montrambert and producing a surplus which is turned on to the distribution system of the Cie. Electrique de la Loire et du Centre, with which this installation is connected. A few words will perhaps be necessary to describe hastily this installation and to explain the connection between these projects and the tests recently made upon the use of producer gas for boiler firing.

In order to utilize this slack and mine waste, which is a coking fuel containing 42 to 45 per cent of moderately fusible ash and 18 to 20 per cent of volatile matter, the Société des Mines de Montrambert has had recourse to gasification, dividing the operation into two

the producer and gives off a gas whose purification is extremely difficult. These low grades of coal can be handled very well in coke ovens and the use of coke in the producers permits an exact regulation of the latter, making it possible to produce a gas which is practically constant in composition and calorific value.

Since this gas is to be used in internal combustion engines its purification is necessary; but the Société des Mines de Montrambert considers that even if the gas were destined for industrial furnaces or boilers it would be worth while in most cases to purify it to a certain extent and to recover, as far as possible, the condensable byproducts and the sensible heat carried by it.

Its installation of two 10-ft. rotating grate producers is therefore completed by purifying and cooling apparatus which insures the deposit of the dust and tar contained by the gas, and which cools and so dries it, pre-heating the air blast for the producers at the same time. In this same apparatus the hot air is saturated with water and the proportion between the weights of water vapor and air furnished to the producer is easily controlled by regulating the temperature of the air.

The gas after its passage through this apparatus is discharged by an extractor into a series of purifying cases and finally passes to a holder from which it is drawn by the suction of the gas engines.

A supplementary installation is added to the equipment mentioned above for the recuperation of the nitrogen content in the coke, of which about 70 per cent is

recovered in the form of ammonia salts. The further recovery of sulphur compounds and other products is being studied.

The works has been in normal operation for about two years, furnishing a monthly production of 200,000 kw.-hr. which is utilized by the Société des Mines de Montrambert or discharged upon the system of the local electric company. Its operation has been so successful that the Société de Montrambert is at present considering the construction of a large works comprising coke ovens and producers capable of handling all the low-grade coal and non-salable waste produced by

FIG. 3. GAS HOLDER

its various mines. It was as part of this project that this company decided in 1919 to experiment upon the use of the available producer gas for the firing of boilers in order to determine whether this gas was suitable under practical conditions for such an application and also to find out what efficiency could be expected of a boiler so fired and whether it would be advantageous to provide batteries of boilers supplying turbo-generator groups instead of internal combustion motors.

For this test the company chose the boiler installed near the battery of coke ovens and which is normally heated by waste gases from the latter. This boiler (Fig. 1) is of the Büttner type (water tube) having a heating surface of 80 sq.m. (about 860 sq.ft.) and is installed in the open air without economizer or feed water heater. It had been in operation for about ten years and the tubes were fouled by the tar and the lamp black deposited by the waste gases coming from the coke ovens. Prior to the test the interior of the tubes was cleaned, but it was impossible to reach the exteriors in order to remove scale and soot, which fact probably reduced the boiler efficiency to some extent. The brick setting was in rather poor condition.

For the firing of this boiler the principle of "surface combustion" was used, employing the patented process and equipment of an American firm, the Surface Combustion Co. of New York. This process consists in mixing intimately the gas with the air necessary for its combustion in their exact chemical combining proportions (without excess of either air or of gas) and in projecting this mixture into a porous bed of refractory material at a speed sufficient to avoid any possibility of back firing. Almost instantaneous combustion takes place in contact with the hot surfaces of the refractory pieces composing this bed, which is rapidly brought to incandescence and serves as a source and reservoir of radiant heat.

It is in this form that heat is most penetrant and

the most rapidly absorbed by the object to be heated, although this factor has been frequently lost sight of in the application of gas burners to the firing of boilers.

In the usual boiler practice with the solid fuel firebox not only is the boiler heated by absorption from the hot products of combustion, but also to a very considerable extent by radiation from the surface of the fuel bed. Efficiency is lost, however, in the use of solid fuel owing to the large excess of air required for complete combustion, with its consequent lowering of the flame temperature.

In the usual methods of firing boilers with gas the reverse is true and a more or less high flame temperature is obtained, but this flame is practically non-radiant. Contact of the hot gases or of the flame itself with the tubes is therefore relied upon for heating the boiler, which thus becomes to all intents and purposes practically a waste heat boiler.

If, therefore, we can utilize the efficiency of generation obtained by perfect control of a gas mixture with consequent high flame temperature, and at the same time present an efficient radiant surface to the boiler, we shall realize the combined advantages of firing with gaseous and solid fuels. This was the object in view.

Fig. 4 represents a longitudinal section of the boiler firebox transformed for the use of gas. The gas was drawn from the holder by a Roots blower, which raised it to a pressure of 12 to 16 in. of water and transmitted it through an overhead pipe line to the boiler. This pressure is employed in the inspirator A, consisting

FIG. 4. LONGITUDINAL SECTION OF BOILER WITH GAS BURNER

of a gas nozzle and Venturi throat, to inspire from the atmosphere the full quantity of air necessary for the complete combustion of the gas. The high velocity of the gas and air passing through the throat completes their intimate mixture and this mixture is delivered, under pressure, to the cast-iron burner B, which discharges it at a suitable velocity into the refractory bed C. This burner is designed to present the minimum of metallic surface to the radiation from the furnace and its cross-section is sufficiently great to insure the rapid conduction of any heat absorbed to the exterior, where this heat is dissipated to the air by means of cooling fins cast integral with the body of the burner.

A feature to be noted is that the inspirator *A* maintains automatically constant the proportions of air and gas furnished to the burner without the need for any attention on the part of the operator. The gas consumption and therefore the rate of evaporation of the boiler may thus be regulated by the operation of a single valve *V* in the gas supply line as long as the quality of the gas remains approximately constant. By this means combustion under the most efficient conditions is assured—i.e., without excess of air or of gas and at the highest possible temperature.

Since a draught is not necessary for the proper operation of this system, but on the contrary is rather harmful, the boiler was isolated from its stack and a small brick flue was built against the rear of the setting, mounting to the same height as the latter, and into the bottom of this flue the waste gases were discharged from the breeching. A small damper in the

FIG. 5. EXTRA PUMP AND RESERVOIR INSTALLED TO MEET INCREASED EVAPORATION UNDER GAS FIRING

flue permitted the control of the pressure in the boiler setting.

During the period of installation of the gas-burning equipment the boiler was shut down. It was therefore entirely cold when first started up and contained water up to the normal operating level. The burner was lit quite easily by means of a small torch of oily waste. At the end of forty minutes of heating the boiler was in full operation at 120-lb. pressure as was indicated by steam escaping from the safety valve. This speed of heating demonstrates the extreme flexibility in responding to variation of load which a battery of boilers fired with gas by the surface combustion system would have.

A continuous test of the boiler at normal pressure (6.5 kilos — 93 lb.) was next attempted, but at the end of a short time it was discovered that the injector and the feed pump with which the boiler was equipped taken together were of a capacity insufficient to supply its demand when in full operation with gas firing. A second and more powerful pump was installed and a new pipe line was run doubling the capacity of the water feed. Even with these arrangements the factor limiting the production of steam was still the feed water equipment and not the boiler itself, and it was impossible to allow it to operate continuously at its maximum evaporative capacity. This latter is apparently in the neighborhood of 30 kilos of steam per hr. per sq.m. of heating surface (6.15 lb. per sq.ft.). A 24-hr. test was, however, obtained during which the

average rate was 23.75 kilos per sq.m. (4.9 lb. per sq.ft.), which is about double the normal steam production for this type of boiler. The water feed was measured by a meter known to be correct and the gas by observations made upon the gas holder, which during this test was used to supply only the boiler. The boiler was connected in upon a steam line at 6½ kilos and the pressure during the test was therefore maintained at this figure.

The average production of steam was found to be 1,900 kilos per hr. (4,200 lb.) with a gas consumption of 2,485 cu.m. (87,800 cu.ft.) per hr. measured at the holder and of 1,990 cu.m. (70,300 cu.ft.) per hr. measured by the nozzle in the inspirator. Since the temperature at the holder averaged 49 deg. C. and the gas was saturated with water vapor at this temperature, the consumption calculated by the holder was corrected for the normal pressure and temperature at the works laboratory, account being taken of the volume of water vapor contained. The above figure then becomes 1,970 cu.m. per hr. (69,600 cu.ft.) at 718 mm. and 15 deg. C., which checks quite well with the consumption calculated from the pressure at the inspirator nozzle, or, correcting to 0 deg. C. and 760 mm., 1,765 cu.m. (62,300 cu.ft.) per hr. In round figures, therefore, 1 cu.m. of gas produced 1 kg. of steam (16 cu.ft. of gas produced 1 lb. of steam). The calorific value of the gas was controlled by a Junkers calorimeter and varied during the test from 813 (minimum) to 902 (maximum) calories per cu.m. (91.3 to 101 B.t.u. per cu.ft.)—average 856 at 15 deg. C. and 718 mm. (96.3 B.t.u.). From these figures the over-all thermal efficiency of the boiler is figured as equal to 73.3 per cent. This efficiency could without doubt be improved appreciably with a clean boiler well constructed with a view to economy. The coke consumption of the producer averaged 450 kilos (1,000 lb.) per hr., 45 per cent ash content, calorific value not over 4,000 calories per kilo (7,200 B.t.u. per lb.).

The pressure and temperature of the flue gases were measured; near the bridge wall a pressure of 5 mm. water was found and immediately before the damper in the small chimney there was a suction of 5 mm. At the same place the temperature of the gases was 344 deg. C. on Dec. 20 and 354 deg. C. on Dec. 21.

Frequent flue gas analyses were made—the average of these was 17.9 per cent CO, with sometimes several tenths per cent CO and at other times a slight percentage of oxygen according as the gas varied in quality.

The samples taken at the bridge wall checked well with those at the breeching, showing that combustion was complete in the firebox before contact of the gas with the tubes.

In view of the satisfactory results which these first tests have given, the Société des Houillères de Montrambert et de la Béraudière is considering at present the use of producer gas for firing an important battery of boilers as a part of a large project for the utilization of its waste coal.

The installation was made by the Cie. Générale de Construction de Fours of Paris, employing the patented process and equipment of the Surface Combustion Co. of New York.

The writer wishes to acknowledge his indebtedness to M. Blache of the Société de Montrambert for much of the information above, and for the many courtesies extended to him during the tests.

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Cellulose Esters.—Cellulose esters are prepared by subjecting to the usual process of esterification a cellulose derivative obtained on treating cellulose with nitric acid in the presence of nitrobenzene. In an example, cotton is treated with a mixture of nitric acid and nitrobenzene, and the product, after washing and drying, is warmed with a mixture of glacial acetic acid, acetic anhydride and bromine or other catalyst, as indicated in the parent specification; the acetate is separated in the usual manner by dilution with water, and may be hydrolyzed before or after separation. Specification 1,156—1914 is referred to. (Br. Pat. 145,524—1919. AKT. GES. FÜR ANILIN FABRIKATION, Treptow, Berlin, Sept. 1, 1920.)

Dust Removal From Gases and Vapors.—Dust is removed from gases and vapors by means of a rotary electric field between a number of stationary electrodes. These may be arranged about the axis of a casing, in number dependent on the kind of the field used; preferably the number of electrodes is a multiple of the number of phases of the alternating supply system, so that the field is multipolar. The electrodes may be arranged longitudinally with reference to the casing. They may be surrounded with insulating material. In the center of the rotating field there may be arranged either a rod having a higher dielectric constant than the gases, or a conductive rod connected to the neutral point of the polyphase supply system. Alternatively, a combination of these devices may be employed, in the form of a conductor surrounded by a glass cylinder, or of a stream of water. Reference is made to an arrangement having electrodes rotated by means of a rotary electro-magnetic field. (Br. Pat. 145,585 1919. W. NORTH, Hanover, Germany, Sept. 1, 1920.)

Cellulose Acetate Compositions.—A composition for use as a coating material, or in the manufacture of artificial silk or films, or as a varnish, and which can be cast or molded, consists of cellulose acetate and the aggregate of fatty acids extracted from coconut oil. A volatile solvent such as chloroform, acetone, acetylene tetrachloride, or chloroform and alcohol, is used in the manufacture of the composition; and the proportions of solvent and of fatty acid are varied according to the purpose for which the composition is to be employed. (Br. Pat. 146,212—1919. BRITISH CELLULOSE & CHEMICAL MANUFACTURING CO., London, Sept. 8, 1920.)

Obtaining Copper and Nickel Electrolytically.—In treating copper-nickel alloys or concentrates in chloride solutions, an oxidizing agent such as chlorine is introduced at intervals or continuously, so that the copper deposited at the cathode is equal in amount to that dissolved from the alloy constituting the anode. The solution may contain hydrochloric acid or a chloride such as common salt. Initially, for instance, it may be a solution of 135 g. crystallized cupric chloride per liter of 25 per cent hydrochloric acid. At a low electric

pressure, copper and nickel dissolve from the anode as sub-chlorides, no copper being deposited until a large part of the cupric chloride is reduced. No chlorine is added until deposition has brought down the proportion of copper in solution to about 4 per cent. The anode may contain 30 per cent of copper. When the solution is sufficiently rich in nickel, it is treated for the recovery of this metal by known means. (Br. Pat. 145,600—1919. P. GOLDBERG, Treptow, Berlin, Sept. 1, 1920.)

Aminophenol Derivatives.—*N*-dioxypentyl-*p*-aminophenol and its alkyl ethers are obtained by the reaction of *p*-aminophenol or its alkyl ethers with α -monochlorhydrin or glycid; the process may be effected in the presence of a neutral solvent or substances binding hydrochloric acid. Examples are given of the preparation of *n*-dioxypentyl-*p*-aminophenol, *n*-dioxypentyl-*p*-anisidine, and *n*-dioxypentyl-*p*-phenetidine; *n*-dioxypentyl-*p*-aminophenol may be used as a photographic developer, and *n*-dioxypentyl-*p*-phenetidine has therapeutic properties. Instead of α -monochlorhydrin, epichlorhydrin may be used, the resulting chloro compound being saponified by alcoholic potash. (Br. Pat. 145,614—1919. E. KOLSHORN, Dahlem, Berlin, Sept. 1, 1920.)

Isolation of the Alkaloids of Lobelia Inflata.—Three alkaloids, termed α -, β -, and γ -lobeline, are isolated from the crude alkaloid of *Lobelia inflata* by dissolving the crude product in hydrochloric acid, crystallizing out the difficultly-soluble hydrochloride of β -lobeline, and extracting the hydrochloride of α -lobeline from the mother liquor by means of chloroform. The chloroform solution is mixed with soda solution, the chloroform evaporated off, and the α -lobeline crystallized out; it is formulated as $C_{11}H_{15}O_2N$. The β - and γ -lobeline are not crystalline. The crude alkaloid employed may be obtained by extracting the drug by alcohol, distilling off the alcohol, dissolving the bases in dilute acid, neutralizing the acid solutions by alkali and extracting with ether; or the first extract may be made with ether or benzene. This process may be modified by using carbon tetrachloride, trichlorethylene, acetylene tetrachloride, etc., instead of chloroform for extracting α -lobeline hydrochloride from the mother liquor from which β -lobeline hydrochloride has been crystallized out. (Br. Pat. 145,621 and 145,622—1919. C. H. BOEHRINGEN SOHN, Ingelheim-on-Rhine, Germany, Sept. 1, 1920.)

Dyeing With Vat Dyes.—In dyeing animal fibers or mixed goods with vat dyes, the products of alkali hydrolyses of vegetable or animal albumins similar to protalbinic or lysalbinic acids, or their alkali salts, are added to the dye vats; brighter shades are thereby obtained and the fibers become more soft, elastic and glossy. The vats may be made neutral or slightly acid. In an example, a vat contains indigo MLB, sodium hydrosulphite, and hydrolyzed glue or casein, and is neutralized by formic acid. (Br. Pat. 145,674—1919. C. BENNERT, Grunau, near Berlin, Sept. 1, 1920.)

Artificial Threads, Ribbons, Films and Sheets.—In the manufacture of artificial threads and of ribbons, films or sheets from viscose, the solution is introduced through suitably shaped apertures into a precipitating bath consisting of waste sulphite-cellulose lye to which has been added a mineral acid or an acid salt—for example, sulphuric acid, sulphurous acid or hydrochloric acid. The waste lye obtained in the manufacture of

"sulphite ethers" may also be used. It is preferred to use a waste lye which is free from lime—for example, a sodium sulphite lye obtained when the wood is boiled with sodium bisulphite, or "by conversion of sodium salts from the waste lye of lime"; and the lye should be concentrated before use. Hardening agents such as formaldehyde or sulphate of alumina, and glue, seaweed mucilages, etc., may be added to the precipitating bath; by such additions the sensitiveness of the threads, etc., to water and their capacity for dyeing can be favorably affected. (Br. Pat. 145,627—1919. M. MUELLER, Finkenwalde, near Stettin, Sept. 1, 1920.)

Tanning.—Hides and skins are stated to be tanned by the application of constituents extracted from vegetable substances such as wood, straw and the like by means of alkaline liquids; or by formaldehyde or the salts of heavy metals such as chromium and iron, in the presence of such constituents. In an example, an extract obtained by boiling straw in soda-lye is mixed with iron-alum, in which case a yellow deposit is slowly brought down. This suspended agent is used for tanning. (Br. Pat. 145,742—1919. H. BREUER, Bonn-on-Rhine, Sept. 1, 1920.)

Refining Tin and Antimony.—Crude tin is refined by treating with dry chlorine which may be obtained by vaporizing liquid chlorine, filtering the liquid product, treating with water to decompose the chlorides of antimony, arsenic and sulphur, filtering again, and recovering tin from the pure solution of stannic chloride, for instance, by reduction to stannous chloride and electrolysis. To separate the antimony, the process is modified by heating the reaction vessel to 115-120 deg. when the antimony pentachloride is decomposed into chlorine and solid trichloride, which is therefore removed in the first filtration. In a similar manner antimony is separated from metals such as lead, and is obtained as pentachloride alone when tin does not occur among the impurities. (Br. Pat. 145,789—1919. G. BONNARD, Plombière-St. Marcel, Savoie, France, Sept. 1, 1920.)

Gallolactates, Tannolactates.—Gallolactates and tannolactates of the alkaline-earth metals, magnesium or aluminum are obtained by heating normal lactates with gallic, tannic or gallotannic acid, or basic tannates or gallates with lactic acid, in dilute alcohol, dilute acetone or mixtures thereof. Examples are given of the preparation of calcium tannolactate, calcium gallolactate, barium tannolactate, strontium tannolactate, aluminum tannolactate and magnesium tannolactate. The products are practically insoluble in water and alcohol, are slowly decomposed by dilute acids, and have therapeutic properties. (Br. Pat. 146,234—1919. E. KOLSHORN, Dahlem, Berlin, Sept. 8, 1920.)

Acyl Cyanamides.—Cyanamides of α -halogenfatty acids are obtained by reaction of halides of α -halogenfatty acids with metal cyanamides in aqueous solution or suspension. An example is given of the preparation of diethylbromacetyl cyanamide from diethylbromacetyl chloride or bromide and sodium cyanamide; α -bromisovaleryl cyanamide is also specified. Instead of sodium cyanamide, the cyanamides of calcium, silver, copper, lead, etc., may be employed. (Br. Pat. 146,289—1919. FARBENFABRIKEN VORM. F. BAYER & Co., Leverkusen, near Cologne, Sept. 15, 1920.)

Separating Mixtures of Gases.—To separate into its constituents the gas obtained in the dry distillation of fuel, the gas is first freed from tar, ammonia and

benzene, and then passed over substances having a large superficial area—for example, absorbent carbon—in which the constituents are selectively absorbed; this selective absorption is facilitated by passing the gas over a plurality of absorbent masses at different temperatures. The process is particularly applicable to the separation of ethylene, in which case it is preferred to cool the absorbent mass to a temperature between 0 and 20 deg. C.; the fraction enriched with respect to ethylene is if necessary expelled, collected and re-absorbed as before to obtain a further enrichment, and this process may be repeated. (Br. Pat. 146,332—1919. GOLDSCHMIDT AKT. GES., Essen, Sept. 15, 1920.)

Linoleum.—A composition for making linoleum consists of cellulose treated with alkaline lyes and vapor of carbon bisulphide, a rubber-like product obtained by heating glue or carbohydrates with glycerine and saponified resin. These ingredients are mixed, heated, treated with hardening agents, such as formaldehyde, chrome salts, alum, tannin, etc., and kneaded and rolled up with cork meal, sawdust or other finely powdered cellulose and coloring matter. The mass can be applied to a backing of paper or not, as desired. (Br. Pat. 146,367—1919. PHENOLEUM GES., Berlin, Sept. 15, 1920.)

Pigments.—Ultramarines and lakes are made by liberating, in a mass of china clay, alumina and/or silica; and, in the case of ultramarines, heating the product with a polysulphide of sodium; in the case of lakes, combining it with acid or basic aniline coloring matters, according as alumina or silica predominates. After treatment with acid sulphate of soda solution, sodium carbonate solution is added to precipitate alumina. The paste is filtered and the residue, after washing, is treated with sulphides of sodium and air-calcined to produce ultramarine or heated to boiling point with a solution of coloring matter to produce lakes. To obtain siliceous blues the product of the acid sulphate reaction is extracted with water to remove the aluminum sulphate and the residue treated with carbonate as before. According as acid or basic colors are employed for producing lakes, the china clay is treated to liberate alumina or silica respectively as described above. (Br. Pat. 146,402—1919. R. D. LANCE, Paris, Sept. 15, 1920.)

Zinc Sulphide; Lithopone.—Pure zinc sulphide is prepared from a soluble zinc salt, by passing sulphuretted hydrogen into the solution after the addition of such quantity of oxide or carbonate of the alkali or alkaline earth metals that the final solution when all the zinc sulphide has been precipitated remains slightly acid. The zinc solution employed may be prepared from any zinc-bearing materials, but when obtained by acting on zinc blende with hydrochloric acid and eliminating impurities, the sulphuretted hydrogen evolved during the solution of the ore may be used subsequently to precipitate the zinc sulphide. The most suitable oxide or carbonate to employ is magnesia or magnesium carbonate, since hydrochloric acid and magnesia may be regenerated, by heating with steam, from the magnesium oxychloride obtained by the addition of magnesia to the magnesium chloride solution left after the separation of the zinc sulphide. The latter is calcined at a high temperature, washed and ground, and by incorporating with barium sulphate yields lithopone. (Br. Pat. 146,410—1919. C. CLERC, Paris, and A. NIHOUL, Villex-neuve le Roi, Sept. 15, 1920.)

Program American Institute of Chemical Engineers

THE thirteenth winter meeting of the A.I.C.E. will be held at New Orleans, La., Dec. 5 to 8, after which the salt, sugar, molasses and sulphur industries in the immediate district will be visited. Reservations on train 137 leaving the Pennsylvania station, New York, at 3:40 p.m., Friday, Dec. 3, should be made with F. E. Dodge, Room 1430, The Barrett Company, 17 Battery Place, New York City. The local committees, composed of Lezin A. Beemel, Charles E. Coates, William C. Ermon and Charles S. Williamson, Jr., have arranged a little Mardi Gras of intellection which will begin with a parade through the streets of the city as follows:

SUNDAY, DECEMBER 5

2:30 P.M. Automobile ride seeing New Orleans.

MONDAY, DECEMBER 6

Meeting at the Cabildo.

9 A.M. Business session. Canvass of ballots for officers. Reports of officers and council. Reports of committees.

10 A.M. Reading of papers:

"Recent Advances in the American Sulphur Industry," Dr. R. F. Bacon.

"The Conservation of Heat Losses as Applied to Power and Heating Systems," E. R. Weidlein.

"The Sulphuric Acid Fume Problem," James R. Withrow and F. C. Vilbrandt.

"Costs—A Study of Factory Economics," A. G. Peterkin. "Operating Variations in Sugar Production as Indicated by Some Plantation Data," Lezin A. Beemel.

2 P.M. Alternate excursions: Visit to plant of Southern Cotton Oil Co. and Sugar Refinery, or Visit to Water Filtration Plant of New Orleans.

8 P.M. Meeting at the Cabildo.

"Resources of the State of Louisiana," N. L. Alexander, Chief of Conservation Commission.

"Sewage, Water Purification and Drainage in New Orleans," George G. Earle, Chief Engineer and Superintendent, Sewerage and Water Board.

Smoker.

TUESDAY, DECEMBER 7

Meeting at the Cabildo.

9 A.M. Business session.

10 A.M. Reading of Papers:

"Lubrication of Concrete," Maximilian Toch.

"The Treatment of Sewage by Aëration in the Presence of Activated Sludge," E. Bartow.

"The Federated American Engineering Societies and the Institute," James R. Withrow.

"The Salvaging of Sag Paste," C. B. Morey.

"Studies in Evaporator Design—IV. Some Data From the Horizontal Tube Evaporator," W. L. Badger.

1:30 P.M. River trip and inspection of port facilities—tendered by the Board of Commissioners of the Port of New Orleans. The plant of the U. S. Industrial Alcohol Co. and of Penick & Ford, largest molasses canners in the world, will be visited.

7 P.M. Subscription Dinner at Antoinettes.

11 P.M. Leave New Orleans for visit to salt and sulphur mines.

WEDNESDAY, DECEMBER 8

7:08 A.M. Arrive at Lake Charles. Breakfast and auto ride to sulphur mines—tendered by the Chamber of Commerce of Lake Charles.

11:20 A.M. Leave Lake Charles for New Iberia.

2 P.M. Arrive at New Iberia.

Visit to salt mines during afternoon and returning to New Iberia at 6 P.M.

THURSDAY, DECEMBER 9

1:59 A.M. Leave New Iberia.

2:42 A.M. Arrive at Franklin. Visit to sugar factory and sugar plantation during the forenoon.

12:36 P.M. Leave Franklin.

5:50 P.M. Arrive at New Orleans.

7:40 P.M. Leave New Orleans.

FRIDAY, DECEMBER 10

11:10 A.M. Arrive at Chattanooga, Tenn. Alternate excursions: Auto trip to Lookout Mountain and nearby points of historic interest, or excursion to byproduct coke plant.

7:50 P.M. Leave Chattanooga.

SATURDAY, DECEMBER 11

9:30 A.M. Arrive Roanoke. Visit to blast furnaces of the Virginia Iron, Coal & Coke Co.

12:50 P.M. Leave Roanoke.

5:45 P.M. Arrive at Luray. Visit to the famous Caverns of Luray.

11:30 P.M. Leave Luray for Philadelphia and New York.

Ladies' Program

SUNDAY, DECEMBER 5

2:30 P.M. Automobile ride seeing New Orleans.

MONDAY, DECEMBER 6

2:30 P.M. Visit to State Museum and Vieux Carré, the old French quarter of New Orleans.

8:15 P.M. Theater party.

TUESDAY, DECEMBER 7

1:30 P. M. River trip with inspection of port facilities—tendered by Board of Commissioners of the port of New Orleans.

5:30 P.M. Return.

7 P.M. Subscription Dinner at Antoinettes.

11 P.M. Leave New Orleans for visit to salt and sulphur mines.

The remainder of the meeting—same program as for the men.

New Selling Method in Brick Industry Proposed

A new card of price extras has been adopted by a number of the leading producers of fireclay and silica brick. The plan used follows very closely the percentage method used by plate-steel manufacturers.

Shapes are classified according to cost of manufacture and each class takes a percentage extra over the base price. Thus the extra or up charge on any class of shapes automatically changes with any change in the base price.

A large number of the shapes in common use have been classified according to the costs of production, and it is expected that as further cost figures are obtained a complete list of all shapes in general use can be prepared. This is the first general change in firebrick extras since brick were selling for \$18 to \$20 in 1912 and 1913.

As labor costs represent the larger part of extra costs on special shapes, the increases in wages during the past few years made a change in extras necessary. The classification, while based on recent cost figures, follows quite closely the same percentage of the 9-in. base price as the extras in use when brick sold at \$20.

Loans Dye Collection to University

Dr. Charles E. Munroe, a widely known high explosives specialist, has loaned his collection of dyestuffs to the new chemical laboratory of the George Washington University. The collection is particularly complete.

Current Events

in the Chemical and Metallurgical Industries

Notes on European Chemical Industry

Dr. James F. Norris of the Massachusetts Institute of Technology presented a very interesting and instructive address on "Conditions of European Chemical Plants" at a joint meeting of the Western New York Section of the American Chemical Society and the Niagara Falls Section of the American Electrochemical Society held in Niagara Falls, Nov. 16.

Dr. Norris was a Colonel in the gas service of the United States Army during the war. In the summer of 1918, the gas chemists of the United States Army discovered and developed a new gas which was much more deadly than any gas which had ever been used in warfare. Owing to the possibility of a courier carrying written information falling into the hands of the enemy, Colonel Norris, who was familiar with all the details of manufacture, was intrusted with the personal delivery of these important discoveries to the Allied Commission, and at the same time was to obtain information for the Chemical Warfare Service regarding new discoveries made abroad.

The speaker first discussed the conditions of the chemical industries as he found them in England. Much praise was given the high standard and excellent quality of work produced by the individual unit both in research and in production of important chemicals essential to munitions. The lack of organization, however, was one outstanding feature which was in direct contrast to the way in which the same operations were carried on in America. There were no centralized laboratories, and the small individual laboratories, although under the direction of a capable head, were handicapped by the lack of a sufficient number of assistants and adequate equipment to undertake the problems which arose.

Dr. Norris further stated that some of the English industrial chemical plants which were constructed during the war were the most wonderful he had ever seen. An instance was given where he made a visit to one of the largest contact sulphuric acid plants at the noon hour and the factory was so spotlessly clean and orderly that the women employees ate their lunches and enjoyed their noonday rest seated around an acid tower. This particular plant was operated entirely by women, there being only one man in the entire plant organization.

After the armistice the speaker was privileged to visit German chemical plants in the British, American and French occupied zones. Many instances were cited of the ingenuity of the German chemists in meeting the problems brought about by the war and in developing new processes to use available crude materials in place of common ingredients which could not be obtained.

In one plant near Cologne, where vast quantities of sulphuric acid were made, the supply of pyrites became exhausted. An ample supply of gypsum was available, and the plant chemists stepped to the front and developed a commercial process for making sulphuric acid from gypsum, unheard of previously. Calcium sulphate

and silica sand, with a little clay added for a flux, were heated in a rotary cement kiln to bring about the necessary reaction. The gases drawn off were treated and made available for conversion into the acid, and a good grade of cement was obtained as a byproduct from the slag which came from the kilns.

All of the plants in the occupied territory were in a very orderly condition and in the best of repair. At the cessation of hostilities the plants ceased to produce, and the workmen were given employment in cleaning up and putting the plants in good order. The men in charge showed a willingness to describe in detail the processes which they used in their plant in the manufacture of gases up to the point of naming the catalyzers which were used. With German thoroughness all records of research laboratories and plant operation, as well as all the catalytic agents, were removed from the plants and sent to Berlin before the Allies reached the chemical plants along the Rhine.

The speaker gave a brief description of the process and apparatus used and some of the difficulties encountered in the German plants which manufactured ammonia by the Haber process. He corrected the erroneous report which has been in circulation to the effect that the contact towers used were buried in the ground and stated that the apparatus was all situated above ground, and that the contact towers, which were about 35 ft. high and 3 ft. in diameter, had walls 9 in. thick, in order to withstand the working pressure of hot hydrogen at 200 atmospheres.

In one of the plants visited, the manufacture of synthetic rubber in large quantities was noted. This material was stated to be superior in some respects to the natural product, especially in the manufacture of hard rubber articles.

The close connection between the dye industry and the manufacture of gases and chemicals essential to modern warfare was impressed upon the audience, as well as the future commercial possibilities of some of the hitherto obscure chemicals whose commercial production was highly developed during the war.

Dr. Norris closed his lecture with a number of slides depicting devastated France and showing the deliberate systematic destruction of the French chemical plants by the German forces as they were compelled to retreat during the closing days of the war.

Colloidal and Olfactometry

At the New York Section meeting of the American Chemical Society, Nov. 19, Reston Stevenson presented a preliminary paper on the Maximum Zones of Colloidal by Jerome Alexander, following which Ellwood Hendrick entertained the audience by an appreciation on the nose. Olfactometry has both a humorous and a serious aspect which the chemist should study in conjunction with the psychologist. It is undoubtedly of scientific and industrial importance. The value of foods and many commodities are dependent on odor and taste, which are related. The subject should not be neglected.

Calcium Arsenate Conference Is Called

That manufacturers of calcium arsenate may be more familiar with the methods used in applying this poison to the cotton plant, a conference has been called at the Chemists' Club, in New York, Dec. 6 and 7. At that meeting, which is under the auspices of the Plant Protection Institute, specialists of the Department of Agriculture will explain certain phases of the problem with which it is believed the manufacturers have not a clear understanding.

The Department of Agriculture, in its laboratory at Tallulah, La., developed the most effective method of controlling the boll weevil yet devised. It was found that the boll weevil relied upon the dew on the plant for its liquid. By dusting the leaves of the cotton plant early in the morning with calcium arsenate, it was discovered that the dew could be poisoned sufficiently to kill a large proportion of the weevils. The discovery of this method of boll weevil control led to a very rapid expansion in the demand for calcium arsenate. While the product now has been standardized so as to meet the requirements for cotton dusting, there are still a number of matters which it is believed advisable to talk over with the manufacturers.

Rochester Section, A.C.S., Holds 112th Meeting

The Rochester Section of the American Chemical Society held its 112th meeting Monday evening, Nov. 8, in the Eastman Building, University of Rochester.

Chairman Woodland announced the personnel of the various committees which will have charge of the Spring Meeting of the American Chemical Society, which is to be held in Rochester during the week of April 25, as follows:

Executive Committee: J. Ernest Woodland, Hans T. Clarke, Victor J. Chambers, Harry A. Carpenter, Harry LeB. Gray, Erle M. Billings, Florus Baxter, Herbert Eisenhart, Ivar N. Hultman, Charles F. Hutchison, William Earle, Charles W. Markus, John Howe, Benjamin V. Bush.

Entertainment Committee: Charles F. Hutchison, chairman; Otto I. Chorman.

Transportation Committee: Charles W. Markus, chairman.

Excursion Committee: William Earle, chairman.

Program Committee: Erle M. Billings, chairman; Wilbur Miller, Arthur J. Herty, Felix Elliott, John I. Crabtree, Robert Salter.

Finance Committee: Herbert Eisenhart, chairman; Frank W. Lovejoy.

Publicity Committee: Benjamin V. Bush, chairman.

Hotels Committee: Harry LeB. Gray, chairman; Lincoln Burrows.

Registration and Information: Harry A. Carpenter, chairman; William Line, Otto Cook, Florus Baxter, Mrs. Richard Kruger, Miss Gertrude Reissman, Edward Pickard.

Women's Entertainment Committee: Miss Jane P. Hannock.

Rochester Section Chemical Industrial Show: Ivar N. Hultman, chairman; M. J. Kolb, Mr. Nausman, Mr. Viergiver, Mr. Will, Mr. Story, Mr. Prince, Mr. Leary, Mr. Tucker.

Due to the increased number of National Society members from the Rochester Section, another councilship is allotted to the Section from next Jan. 1. Dr. Hans T. Clarke was unanimously elected to fill this

office. Dr. Clarke is widely known among the chemists of America. He is director of the synthetic-organic chemistry department of the Eastman Kodak Co.'s Research Laboratory. Dr. Clarke is also secretary of the Organic Division of the American Chemical Society. He is the author of many textbooks and papers dealing with organic chemistry.

Dr. John R. Murlin, director of the department of vital economics and chairman of the committee on food and nutrition, National Research Council, delivered an address before a large assembly of chemists, on "Energy and Metabolism." In this lecture the way the human body derives its energy from various classes of foods was clearly brought out by illustrations and demonstrations.

A Research Information Bureau

The National Research Council has established a research information service as a general clearing house and informational bureau for scientific and industrial research. This "service" on request supplies information concerning research problems, progress, laboratories, equipment, methods, publications, personnel, funds, etc.

Ordinarily inquiries are answered without charge. When this is impossible because of unusual difficulty in securing information, the inquirer is notified and supplied with an estimate of cost.

Much of the information assembled by this bureau is published promptly in the *Bulletin* or the "Reprint and Circular Series" of the National Research Council, but the purpose is to maintain complete up-to-date files in the general office of the Council.

Requests for information should be addressed to Research Information Service, National Research Council, 1701 Massachusetts Ave., Washington, D. C.

Engineer Needed for Non-Metals Work in the Bureau of Mines

R. B. Moore, chief chemist of the Bureau of Mines, is having considerable difficulty in locating a mining engineer with experience in non-metals work. He has been authorized to place two non-metals men at the new Tuscaloosa Experiment Station. He has found it difficult, however, to locate men with the required experience and has about reached the conclusion that it will be necessary to employ a mining engineer with good basic training who has not heretofore specialized in non-metals work.

Dr. Moore also is looking for a chemist with training in radio-activity. A chemist with such qualifications is desired to assist Dr. S. C. Lind in his radium work at the experiment station at Reno, Nev.

A.C.S. Advisory Sub-Committee Chairmen on Chemical Warfare Service Named

Chairmen have been selected for the four subdivisions of the American Chemical Society's advisory committee on Chemical Warfare Service matters. Wilder D. Bancroft, of Cornell University, will be chairman of the Research subdivision. W. K. Lewis, of the Massachusetts Institute of Technology, will head the Development subdivision. C. L. Reese, of the du Pont company, has been selected as chairman of the Production advisers, while A. S. Loevenhart, of the University of Wisconsin, will head the Physiological Investigation subdivision.

More Care Needed in the Handling of Chemicals

The Bureau of Explosives of New York City reports that during the three months ended Sept. 30, 1920, there were 624 fires or explosions on common carriers, resulting in property damage of \$222,575.22 and injury to seventeen persons.

The following is a summary of accidents causing fires, personal injuries and property loss during transportation:

Article	No.	Injuries	Property Loss
Acid, sulphuric (oil of vitriol).....	170	1	\$9,444 77

Methanol Plant for British Columbia

The Acetate Products, Ltd., has completed the purchase of the old Liverpool Cannery plant at South Westminster, B. C., and will commence the installation of an up-to-date methanol (wood alcohol) plant at once. The company has obtained a concession for the cutting of alder over a considerable area along the Fraser and Pitt rivers, and, besides methanol, will make acetate of lime, charcoal and several wood-tar products. This is the first methanol plant to be erected on the Canadian Pacific coast; there are to be two plants of a similar nature in eastern Canada, one in Ontario and the other in Quebec.

Fish and vegetables formerly were canned at the Liverpool Cannery, but the plant has been idle for more than two years. The Acetate Products, Ltd., has announced that it will purchase as much machinery as possible locally, but a considerable proportion will have to be purchased in the East, as it is not manufactured on the coast.

Wood Preservatives Must Be Water Soluble*

Effectiveness of substances in preserving wood is dependent on their solubility in water, at least to the extent of producing a toxic water solution. It would seem reasonable to expect that any material which is poisonous enough to kill an organism of any kind must

necessarily be soluble in the body fluids of that organism; and the chief body fluid of timber-destroying fungi and wood borers is water. With very poisonous materials this solubility need not be great; in fact, 1 part in 1,000,000 may be sufficient if the material is poisonous enough.

Wood preservatives now in use are of two distinct types—inorganic salts, such as zinc chloride, which are very soluble in water; and oils, such as the creosotes, which are generally considered to be insoluble. The solubility of creosote is usually considered so slight as to be neglected, but experiments indicate that certain constituents of creosote are sufficiently soluble in water to render it toxic, the others insoluble in water and hence not toxic. The non-toxic oils act as a reservoir for the toxic oils and feed them slowly to the moisture in the wood.

The difference between oil preservatives and inorganic salt preservatives, as far as this theory is concerned, is in their method of retaining the reserve supply of poison. Zinc chloride has no reserve supply, all the material being soluble in the usual amount of moisture present in air-dry wood. Sodium fluoride may have a reserve supply in the form of solid crystals, if applied in a saturated solution. Creosote oil may have a considerable reserve supply stored in the oil itself, this supply being fed to the wood as needed.

Standard Packages for Reagents

The Committee on Guaranteed Reagents of the American Chemical Society is recommending standard packages for reagents in the metric units. The effort is to eliminate wide varieties of packages so that purchases will be made for any particular material in only two or three standard size units which will be 500 grams instead of a pound; 200 grams instead of a half pound, 25 grams instead of the ounce. The chairman of the committee says: "I am hoping that enough orders will be placed in metric units within the next six months to change the basis of purchase within that time. It can be done if all those who have expressed themselves as preferring the metric units will use them in this connection."

Recommended lists are being submitted by the committee for the guidance of purchasers and it hopes that after some experience on this basis satisfactory agreement can be reached that will permit much greater uniformity than has previously prevailed.

Washington Section, A.C.S., Holds Meeting

"The Chemistry of Vitamines" was the subject of the presidential address by Dr. Atherton Seidell before the Chemical Society of Washington, D. C., Nov. 11. Dr. Seidell gave the history of efforts to isolate pure vitamins and described the present status of our knowledge of these substances. He pointed out that at present it appears more likely that vitamins are in nature fairly similar to enzymes rather than that they are pure chemical compounds in the usual sense.

Officers of the Chemical Society of Washington (local section of the American Chemical Society) were elected at this meeting, as follows:

President, William Blum, Bureau of Standards; secretary, J. B. Reed, Bureau of Chemistry; treasurer, F. P. Dewey, Bureau of the Mint, and councillors to the A.C.S., R. B. Sosman, W. D. Collins, W. M. Clark, F. W. Smither and A. Seidell.

*From *Technical Notes*, Forest Products Laboratory.

Relativity and Life

On Thursday evening, Nov. 18, members and guests of the Philadelphia Section of the American Chemical Society filled the auditorium of the Engineers' Club to hear Ellwood Hendrick, president of the Chemists' Club, New York, and consulting editor of *CHEMICAL & METALLURGICAL ENGINEERING*, speak on "Relativity and Life."

In spite of the fact that not more than a dozen men can follow the mathematical paths by which Albert Einstein arrived at his theory of relativity, the principle itself is most simple and is capable of universal application. Mr. Hendrick developed in some detail the thought that this doctrine should not be confined to the realm of cosmic physics, but should be made a controlling factor in our daily lives. The concept that everything is relative—that nothing is absolute that our every thought and deed is influenced by our relations with others—leads to a system of ethics which the speaker showed could be applied to politics, religion, business and law with benefit to all concerned. Carrying the idea further, it is possible to determine the dimensions of many of the factors involved in our social relations, and we thus have a means of measuring these in an approximately quantitative manner at least. It has often been remarked that scientists and engineers seem reluctant to take part in public affairs. Perhaps they have felt that the gulf between was too wide for them to span. If so, it seems that we have in Einstein's theory of relativity the bridge which will unite the fields of science, engineering and politics.

Book Reviews

CHEMICAL REACTIONS. By K. G. Falk. xiv + 211 pp. New York: D. Van Nostrand Co., 1920. Price \$3.

Contrary to the expectation produced by the title, one does not find the law of mass action, the theorem of Le Chatelier, the principle of maximum work or the phase rule. The effect of the intensity factors of energy in the displacement and determination of equilibrium is not considered. The intensity factor of chemical energy (affinity) is mentioned in the first few pages and its importance stated, but throughout the book the capacity factor (valence) is used instead. This, however, criticises merely the outside of the book and classifies the inside. The subject treated is the application of the J. J. Thomson electron theory of valence to E. C. C. Baly's addition theory of chemical reaction.

The author is particularly qualified by his publications and researches to present the electron theory of valence. He develops and applies this theory admirably. With electronic structural formulae, reactions are pictured as they would occur when the first step in a reaction is the union of the reacting substances. The addition compound is generally instable and temporary and a rearrangement gives one or more of several possible resultants. The methods of determining electronic formulae, their significance and the chemical considerations determining the resulting rearrangement are fully discussed. Electrochemical reactions are omitted. Some inorganic reactions are presented but the book will be valuable chiefly to the organic chemist. Reaction is represented as electronic rather than ionic. A distinct contribution to the ionic theory is made by the explanation of the importance of the solvent.

Every modern organic chemist should read this book as an application of modern physical chemistry to organic chemistry. It is ingenious and profound and an amazing wealth of modern research has been digested and incorporated. The author's style is that of a verbal discussion such as a professor's lecture to advanced students. Many

readers will regret that the exposition is not more gradual and that postulates, theories and experimental evidence are not more obviously classified. On page 43, line 4 is one of the rare typographical errors and on page 133, line 21, hydroxyl should be written instead of hydrogen. The book is printed in large type and the elaborate formulæ are distinct.

RESTON STEVENSON.

* * *

SELLING YOUR SERVICES. By George Conover Pearson. 238 pp. New York: Jordan-Goodwin Corporation; 1920. Price, \$2.

In scarcely any field of human activity is the engineer less proficient, on the average, than in selling his services, and in scarcely any other would he find, on the average, greater financial profit through effort expended to increase his proficiency. If what he needs is impetus, inspiration, or in the language of the day "some pep," he will find Mr. Pearson's little book valuable, but if he goes about it after the fashion of any other engineering problem, analyzing it into its component factors, and getting a firm grasp on the fundamental principles, the style and presentation of the subject matter is not unlikely to be unattractive to him. The author principally has in his mind the securing of a position as an executive in general business, and not only does not recognize that positions of a different character call for variations of method, but says plainly that the same method can be applied to any kind of position. Perhaps this is a natural error on the part of the author because of the tendency on the part of industry to attempt to standardize human beings, undeterred by the fact that it is a quite impossible task. Just at present the executive type of mind is the fashion and the technical expert is only considered to have exhibited the full measure of his powers when he has demonstrated his executive ability. Too many scientific men have demonstrated their value to society without possessing executive ability to render assent possible to such a view. However, from reading the book, the technical man may gather useful suggestions as to the most effective procedure in selling his services when the need for doing so may arise.

T. T. READ.

Personal

Dr. ERNEST ANDERSON, for the past three years professor of agricultural chemistry in Transvaal University College, Pretoria, has been appointed professor of general chemistry in the University of Nebraska, Lincoln, Neb.

Dr. W. R. BLOW, professor of biochemistry at the University of California, addressed the California Section of the A.C.S. recently on the subject of "Fat Metabolism."

R. T. CHAMBERLAIN, professor of geology at the University of Chicago, who has recently returned from a trip in the South Seas, spoke before the Chicago Chemists' Club recently on "The Coral Reefs at Samoa."

GEORGE P. GRAY has resigned his position as assistant professor of entomology and chemistry at the University of California, to become chief of the division of chemistry of the newly established Department of Agriculture of the State of California, Sacramento, Cal.

Dr. L. O. GRONDAHL has resigned as professor of physics at Carnegie Institute of Technology, Pittsburgh, Pa., to become director of research with the Union Switch & Signal Co., Swissvale, Pa.

NORMAN C. HILL, who for almost five years was superintendent of acid plants at the Naval Proving Ground, Indian Head, Md., resigned that position on Oct. 4 to become superintendent of acid production with the Monsanto Chemical Works at East St. Louis, Ill. He will have direct charge of contact and chamber plants, muriatic, chlorosulphonic acid, nitric acid and zinc chloride manufacture.

L. E. JACKSON has resigned as chemist and chemical engineer with the Empire Gas & Fuel Co., Bartlesville, Okla., to accept a fellowship at the Mellon Institute.

VICTOR KADISH has resigned the position of superintendent-

ent of the Milwaukee Patent Leather Co. to open an office as consulting chemist in the Trust Building, Milwaukee, Wis. He will specialize on leather problems.

GEORGE H. KIMBER has left the United States Color & Chemical Co., Ashland, Mass., and is now with the Semet-Solvay Co., Syracuse, N. Y.

CLIFFORD S. LEONARD, who received the degree of Ph.D. from the University of Wisconsin in June, has accepted one of the traveling fellowships of the American Scandinavian Foundation, and has sailed for Sweden. He will study chemistry at the Karolin Institute, Stockholm.

Colonel C. W. OTWELL, recently transferred from the Corps of Engineers to the Chemical Warfare Service, is to take command of the proving ground at Lakehurst, N. J.

S. W. PARR, professor of applied chemistry at Illinois University, delivered a talk before the Western Society of Engineers, Chicago, Wednesday, Nov. 10, on "Fuels of the Future."

CHARLES L. PARSONS, secretary of the American Chemical Society, was in Chicago recently.

WILLIAM N. PRITCHARD, formerly with the Calco Co., Bound Brook, N. J., and Harold Hurst, formerly with the LeDoux Co., are now on the staff of the department of chemistry, Cooper Union, New York.

SAUVEUR & BOYLSTON, metallurgical engineers, Abbott Bldg., Harvard Sq., Cambridge, Mass., announce the appointment of H. M. Boylston to the chair of metallurgy in charge of the mining engineering department, Case School of Applied Science, Cleveland, Ohio, where he will be available for consultation. The firm will continue its laboratories and offices in Cambridge under the supervision of Prof. Albert Sauveur.

O. R. SWEENEY has changed his position from professor of chemical engineering and head of the department of chemical engineering at the University of Cincinnati, to professor of chemical engineering and head of the department of chemical engineering at Iowa State College, Ames, Iowa.

I. J. WALDBAUER has left the Redpath Laboratory of E. I. du Pont de Nemours & Co., to be instructor in chemistry at the University of Maine, Orono, Me.

T. K. WEBSTER, vice-president of the Fansteel Products Co., Chicago, has recently returned from a month's sojourn in England.

JOHN A. WILSON has been retained by the Milwaukee Sewage Commission to direct investigations on the dehydration of sludge.

ROBERT F. WOOD has severed his connection with the Sandusky Foundry & Machine Co., and is now with the Monel Metal Products Corp., Bayonne, N. J., as metallurgist.

R. ZELLER has resigned his position as vice-president, secretary and plant manager of the Egyptian Lacquer Mfg. Co., New York City, and is now with the Zeller Lacquer Mfg. Co., Inc.

The following gentlemen have just been elected directors of the Research Corporation: Dr. A. A. Hamerschlag, president of the Carnegie Institute of Technology, Pittsburgh; John C. Pennie, patent attorney, 35 Nassau St., New York, and Ellwood Hendrick, consulting editor of CHEMICAL & METALLURGICAL ENGINEERING. The other directors are: E. H. Hooker, of the Hooker Electrochemical Co., Niagara Falls, N. Y.; Benjamin B. Lawrence, consulting mining engineer, New York City; Charles A. Stone, president of the American International Corp., New York City; Arthur D. Little, of Arthur D. Little, Inc., Cambridge, Mass.; T. Coleman du Pont, of New York City; Frederick A. Goetze, treasurer of Columbia University, New York City; John B. Pine, attorney, New York City; Charles D. Wolcott, secretary of the Smithsonian Institution, Washington, D. C.; George F. Kunz, Tiffany & Co., New York City; Otto H. Kahn, banker, New York City; John J. Carty, of the American Telephone & Telegraph Co., New York City, and Howard Poillon, mining engineer, New York City. E. H. Hooker is president of the Research Corporation and Benjamin B. Lawrence is treasurer.

Current Market Reports

The Chemical and Allied Industrial Markets

New York, Nov. 22, 1920.

Continued slackening of industrial wheels at various points throughout the country has been greatly reflected in the consuming demand during the past week. Irregular trading of a small character is reported and buying power is not specially emphasized in any important direction. Large holders are granting concessions on some items in order to stimulate business, while others are cutting prices in a spirit of competition. In some instances dealers have declared intentions of keeping out of the market until signs of a more stable market present themselves. In short, the spot market is purely a buyers' affair. Smaller chemicals have shown greater weakness than the larger, and it is asserted that the rapidity of declines in several directions speaks well for the establishment of a permanent trading basis in the near future.

Caustic soda was rather quiet during the week and the market weakened on the arrival of large quantities from leading New England mills. Spot prices ranged from \$4@4.15 per 100 lb. Bichromate soda touched a new low level for the year when sales were made at 9c. per lb. Buyers showed no inclination even at these prices to buy freely. Prussiate of soda suffered another sharp decline owing to strong selling competition and reached its lowest price of the year. Trading did not assume active dimensions and holders were eager to do business ranging from 19@20c. per lb. Heavy calcined magnesia is bringing 8@8½c. per lb., the inside figure being the lowest on record for the year. The technical variety is moving quietly at 11c. per lb. Formaldehyde buyers showed no disposition to operate in a large way, regardless of the acute price concessions. Prices last heard ranged from 18@19c. per lb. White arsenic sales were reported in larger volume than any on the list. In one quarter a sale was consummated for 50 long tons November-December shipment at 11½c. per lb. This figure was the cheapest heard in the past few months and could not be judged as the prevailing market price.

COAL-TAR PRODUCTS

The market for the crude products has reflected a steady tendency during the past week, with reports from leading producers showing their output scarcely above the consuming demand. Prospects of any further declines seem to have disappeared and the present market is toward firmness. C.P. benzene in some quarters is available in tank cars at 33c. per gal., and in drums at 36c. The 90 per cent is 28c. in tank cars and 30c. in drums. Toluene is heard at 26@34c. per gal. Solvent naphtha retains its steady tendency at 30@35c. per gal. Cresylic acid is easy and available at 95c.@\$1.15 per gal., depending on grade.

Intermediates suffered some sharp declines owing to persistent reports that tanneries and textile mills have accumulated large supplies of colors and dyes. Dealers have thrown goods on the market at new low levels with only little response from leading consumers. Beta naphthol technical reached its lowest price of the year when sales were recorded at 40c. per lb. Supplies of dimethylaniline are easy and not much interest is shown even with offerings at 72@75c. per lb. Demand for paranitraniline is quiet, with reports current of low stocks on spot. Prices ranged from \$1.10@\$1.15 per lb. Diethylaniline supplies are reported in fair accumulation with the demand small and the market holding steady at prices between \$1.50 and \$1.60 per lb. Monochlorobenzene tone is easy and sellers quote 14@16c. per lb. The demand is limited to small lots.

CRUDE RUBBER

The market for crude rubber continues to present a quiet and dull appearance. Leading consumers are still out of the market and factors report only small lot sales. Heavy

liquidations have been reported around town and there seems to be little hope for an immediate improvement in the situation. Prices continue mostly nominal. Offerings of *ribbed smoked sheets* on spot are noted at 18½c. per lb. and it is intimated that firm bids of 18½c. per lb. would probably be accepted. December prices are quoted at 18½c. per lb. Deliveries over next year remain unchanged and featureless at 21c. per lb. for January-March, 23c. for April-June and 25½c. for July-December.

PHILIP S. TILDEN SAYS:

The following extract is an expression of the present chemical market delivered recently before the members of the Philadelphia Chemical Club, by Philip S. Tilden, sales director of the heavy chemical and acid department of E. I. du Pont de Nemours & Co.:

"As to the future of the chemical business, God knows. If I knew, I would go out and play golf and come back and reap the benefits at the proper time; but again there should be no cause for pessimism. You cannot take care of 111,000,000 people which make up the United States without an expansion in the chemical business. We do not often realize that everything we have on has been treated in some way by chemicals, and without chemicals we could not exist. Therefore, we must forget the temporary dullness and work for the future. Again this is no time for contraction. I do not mean that we should needlessly expand, but we should be ready for what we know is in store for us in the line of increased demands for the articles which we represent. I think less profiteering was seen in the chemical market than in other lines of industry. The bichromates, prussiates and cyanides have, however, given us many sleepless nights since the war began, and we must now bring ourselves to realize that we must again come down to earth and continue in the chemical business along lines in which it is ordinarily conducted. If the buyers realize that we are again on a permanent basis, it appears to me that buying would be resumed in this business as well as in others."

It is evident, from these remarks, that leaders in the chemical industry believe that the time is already past when ruthless profiteers would again try to dominate the chemical market with exorbitant prices. American producers must now look forward to our domestic consumers for the preservation of the chemical industry. There must be more stability and normality in the present market to tempt buyers into active trading. It is to be hoped that stability will be a reality in the near future.

The Baltimore Market

Baltimore, Md., Nov. 20, 1920.

The local market on fertilizer raw materials continues dull, with buyers showing little interest in offerings. About the only sales that are being effected are in distressed lots which can be secured at prices below the nominal market.

The spring prices for bagged goods have finally been approved at Washington as follows: \$5 per unit of ammonia; 80c. per unit available phosphoric acid; \$2.25 per unit of potash.

The fertilizer manufacturers are sending their salesmen out this week to begin campaigning for spring business; their success in securing orders will be the controlling factor in the resumption of movement of raw materials.

ACID PHOSPHATE

The market on this commodity may be quoted nominally at \$17.50 per ton, basis 16 per cent, bulk run-of-pile. A firm offering, however, has been reported this week at \$17 on the basis mentioned above. It is thought by many that the acid phosphate market will show a slight improvement shortly.

POTASH

Shipments of foreign potash continue to arrive intermittently. Contracts for Alsatian salts for forward delivery are now being booked. Arrival of the full quota, however, is uncertain at this time. German potash is coming in more slowly, although arrivals of cargoes are being noted from

time to time at the various ports. A good portion of these German salts are being shipped by the merchants in the United Kingdom. Up to this time we have had no report that Nebraska producers have booked contracts for future delivery. The market on the various potash salts may be quoted nominally: muriate \$2.10 per unit, manure salts and kainit at \$1.90 per unit, all c.i.f. Atlantic ports. A sale was reported this week, at a Southern point, of a round lot of manure salts at \$1.95 per unit c.i.f. Southern port.

NITRATE OF SODA

This commodity is quoted nominally at \$3 per 100 lb., ex vessel Northern and Southern Atlantic ports. It is quite possible that the importers would entertain a bid somewhat lower than this price on a round tonnage for delivery prior to Jan. 1. A number of fertilizer manufacturers secured their requirements for the spring during last summer at a price averaging \$3.70 per 100 lb.

SULPHATE OF AMMONIA

The last price noted on this material was a resale at \$4.50 per 100 lb., bulk basis 25 per cent, f.o.b. shipping point. A comparatively small tonnage of this material is to be had on the open market.

FISH SCRAP

Many of the factories on the Chesapeake Bay have discontinued fishing for the year owing to the recent light catch on the approach of cold weather. Due to indifference on the part of buyers machine-dried, unground fish scrap has again declined and may be quoted today nominally at \$4 per unit of ammonia and 10c. per unit b.p.l. delivered Baltimore, in buyers' bags, for prompt shipment. There is a rather heavy accumulated stock of menhaden fish oil at this time, and the market on this commodity has also dropped and is today offered nominally at 40c. per gallon in tierces.

The Iron and Steel Market

Pittsburgh, Pa., Nov. 19, 1920.

Steel production by the independents is decreasing at a decidedly rapid rate, as many are not operating at over 50 or 60 per cent of capacity. In occasional instances the production of ingots is extremely light, but with finishing mills operating at a moderate rate on semi-finished steel accumulated during the period of car shortage. The Steel Corporation's operations are well maintained and are probably at a higher rate than that of last August and September, when there was considerable restriction on account of fuel shortage.

There is a fresh run of cancellations of finished steel contracts and of instructions to suspend or postpone contract shipments. Possibly on this account, or possibly because so little business is offered as an incentive, the independent mills as a class show little disposition to reduce their prices. Bars, shapes and plates are regarded as being on the basis of 3c. in the independent market, when the Steel Corporation prices are 2.35c., 2.45c. and 2.65c. respectively. Even sheets, which were declining continuously and rapidly for weeks, have shown little recession in the past week. Tubular goods remain very strong.

STEEL AND OTHER INDUSTRIES

Opinions in the steel trade as to the future of the market have been undergoing a rapid change of late, in the direction of expectations that the readjustment and depression will last longer than was expected. The opinions commonly expressed a few weeks ago were based upon what was observed in the steel industry rather than upon what was occurring in industry and finance generally. It was noted that the consumptive demand for steel kept up rather well, and it was inferred that with a little readjustment in prices and perhaps a period of a few weeks of slack operation the market would be found adjusted and buyers would begin taking hold again. Predictions were quite common, though by no means universal, that the decline in pig iron and steel prices would have run its course by March or April, with a buying movement and a stiffening in prices immediately following.

No such view is now entertained. It is now recognized that the reason the manufacture and consumption of steel continued heavy long after many industries had become almost idle was not because the industry was entitled to continued exemption but because its momentum had carried it for a longer period of time. The force had been spent more slowly because there had been the succession of restrictive influences to production—the steel strike that began Sept. 22, 1919, then the coal strike and then the railroad strikes. The present view is that the iron and steel trade will have to undergo readjustment the same as other industries, and that it cannot become really active again until other industries are active. It is possible, but improbable, that the iron and steel industry could readjust so rapidly as to be ready for business on the new basis within a very few months, but even if so it would have to wait until industrial and financial conditions generally are readjusted, and the process will admittedly take quite a while.

The present view as to the iron and steel future is that through a large part of next year there will be more or less industrial depression, with a real revival in iron and steel buying being early if it occurs in the fall of the year. The present stagnation in buying cannot of course continue for any length of time. There is always consumption, but just after a period of high pressure almost all buyers are able to refrain from making any fresh commitments for a time. Such buying will be from hand to mouth and will not be broad enough to cause prices to advance or stiffen from whatever level they may have declined to.

PIG IRON PRICES

Despite the firmer attitude the merchant furnaces recently suggested they intended to display, waiting for actual inquiries of importance before making further cuts in prices, the pig iron market has slid off again, bessemer being off \$2 and basic and foundry \$1, making the market now quotable as follows: bessemer, \$10; basic, \$37.50; foundry, \$39 f.o.b. valley furnaces, freight to Pittsburgh being \$1.96. The declines occurred with little incentive being presented by way of inquiry. There was hardly any bessemer sold and little basic, while the \$39 price on foundry iron was developed by a sale of 500 tons, for delivery through the remainder of the year to the Standard Sanitary Manufacturing Co.

Declines from the top points reached last August are now \$8.50 in bessemer and \$11 each in basic and foundry. Predictions common only a few weeks ago that the bottom would be reached at between \$30 and \$35 have disappeared. The debate now is as to whether or not the market will break through the Industrial Board prices. Those prices were \$25.75 for basic, \$26.75 for foundry and \$27.95 for bessemer. The furnacemen grudgingly adopted them when promulgated March 21, 1919, and adhered to them for more than six months. It is quite impossible now to make any appraisal as to where the pig iron market can go, because the coke market has refused to give an idea as to where it will go, Connellsville furnace coke for spot shipment being scarcely down to \$8, while in April, 1919, it sold at \$3.60 and in May, 1915, at \$1.50.

STEEL PRICES

It is now not entirely improbable that eventually, and before there is any general upward swing, even the United States Steel Corporation's steel prices will decline. For a long time the trade generally held to the view that whenever a readjustment in steel prices should come it would consist simply in independent prices declining to the Steel Corporation or Industrial Board level. The independents are holding their prices above the Steel Corporation level so well that it seems improbable they will decline to the corporation level until conditions require that all prices should decline. The corporation would have no occasion to reduce its prices for a long time. Even though its order books should not permit it to operate full, it would be operating at much higher rates than the independents, nor would the corporation be much disposed to reduce its prices without a reduction in costs, but the general readjustment in the country is so extensive that reductions in costs are not improbable eventually.

Soda ash, light .. 100 lb.	2.05 - 2.10	2.20 - 2.40
Soda ash, dense .. 100 lb.	2.50 - 2.75	3.00 - 3.25
Sodium acetate .. lb.	0.08 - 0.08 1/2	0.08 - 0.09
Sodium bicarbonate .. 100 lb.	2.90 - 3.00	3.25 - 3.50
Sodium bichromate .. lb.	0.09 - 0.09 1/2	0.09 - 0.10
Sodium bisulphate (nutre cake) .. ton	7.00 - 7.50	8.00 - 11.00
Sodium bisulphate powdered, U. S. P. .. lb.	0.64 - 0.07	0.71 - 0.08
Sodium borate (borax) .. lb.	0.81 - 0.08 1/2	0.09 - 0.09 1/2
Sodium carbonate (soda) .. 100 lb.	1.85 - 2.00	2.15 - 2.25
Sodium chlorate .. lb.	14 1/2 - 15	15 1/2 - 16 1/2
Sodium cyanide, 96-98 per cent .. lb.	26 - 27	28 - 30
Sodium fluoride .. lb.	20 - 20 1/2	21 - 22
Sodium hydroxide (caustic soda) .. 100 lb.	4.00 - 4.10	4.30 - 4.50
Sodium hyposulphite .. lb.	2.50 -	3.25 - 0.04
Sodium molybdate .. lb.	3.00 -	3.75 -
Sodium nitrate .. lb.	0.71 - 0.08	0.08 - 0.08 1/2
Sodium peroxide, powdered .. lb.	35 - 40	42 - 45
Sodium phosphate, dibasic .. lb.	0.31 - 0.04	0.04 - 0.05
Sodium potassium tartrate (Rochelle salts) .. lb.		33 - 35
Sodium prussiate, yellow .. lb.	19 - 20	20 1/2 - 21
Sodium silicate, solution (40 deg) .. lb.	0.11 - 0.13	0.12 - 0.13
Sodium silicate, solution (60 deg) .. lb.	0.21 - 0.03	0.03 - 0.04
Sodium sulphate, crystals (Glauber's salt) .. 100 lb.	2.15 - 2.50	2.60 - 2.75
Sodium sulphide, crystal, 60-62 per cent (cone) .. lb.	0.7 - 0.07 1/2	0.07 1/2 - 0.08
Sodium sulphite, crystals .. lb.	0.04 - 0.04 1/2	0.04 1/2 - 0.05
Strontium nitrate, powdered .. lb.	20 - 20 1/2	21 - 22
Sulphur chloride, red .. lb.	0.08 - 0.09	0.10 - 0.10 1/2
Sulphur, crude .. ton	16.00 - 20.00	
Sulphur dioxide, liquid, cylinders .. lb.	0.09 -	10 - 12
Sulphur (sublimed), flour .. 100 lb.		3.70 - 4.35
Sulphur, roll (brimstone) .. 100 lb.		3.40 - 3.90
Tin bichloride, 50 per cent .. lb.	18 - 19	50 - 51
Tin oxide .. lb.		19 - 20
Zinc carbonate, precipitate .. lb.	16 - 18	13 1/2 - 14
Zinc chloride, gran. .. lb.	12 - 13	13 1/2 - 14
Zinc evanide .. lb.	45 - 49	50 - 60
Zinc dust .. lb.	12 - 13	14 - 15
Zinc oxide, XX .. lb.	10 - 10 1/2	11 - 11 1/2
Zinc sulphate .. lb.	0.31 - 0.33	0.04 - 0.06

Coal-Tar Products

NOTE: The following prices are for original packages in large quantities:

Alpha naphthol, crude .. lb.	\$1.10 -	\$1.15
Alpha naphthol, refined .. lb.	1.45 -	1.50
Alpha naphthylamine .. lb.	.44 -	.46
Aniline oil, drums extra .. lb.	.26 -	.27
Aniline salts .. lb.	.32 -	.33
Anthracene, 80% in drums (100 lb) .. lb.	.90 -	1.00
Benzaldehyde (f. f. c.) .. lb.	2.00 -	2.10
Benzidine, base .. lb.	1.15 -	1.20
Benzidine sulphate .. lb.	1.10 -	1.15
Benzoic acid, U. S. P. .. lb.	.80 -	.85
Benzonitrile, U. S. P. .. lb.	.80 -	.90
Benzene, pure, water-white, in drums (100 gal) .. gal	.45 -	.40 1/2
Benzene, 90%, in drums (100 gal) .. gal	.33 -	.38 1/2
Benzyl chloride, 95-97%, refined .. lb.	.35 -	.40
Benzyl chloride, tech .. lb.	.25 -	.35
Beta-naphthol benzoate (nominal) .. lb.	3.50 -	4.00
Beta-naphthol, sublimed (nominal) .. lb.	.75 -	.80
Beta-naphthol, tech (nominal) .. lb.	.40 -	.45
Beta-naphthylamine, sublimed .. lb.	2.25 -	2.40
Cresol, U. S. P., in drums (100 lb) .. lb.	.18 -	.19
Ortho-cresol, in drums (100 lb) .. lb.	.23 -	.25
Cresylic acid, 97-99%, straw color, in drums .. gal	1.10 -	1.15
Cresylic acid, 95-97%, dark, in drums .. gal	1.05 -	1.10
Cresylic acid, 50%, first quality, drums .. gal	.65 -	.75
Dichlorobenzene .. lb.	.07 -	.10
Diethylaniline .. lb.	1.45 -	1.50
Dimethylaniline .. lb.	.75 -	.80
Dinitrobenzene .. lb.	.30 -	.37
Dinitrochlorobenzene .. lb.	.27 -	.32
Dinitronaphthalene .. lb.	.42 -	.45
Dinitrophenol .. lb.	.40 -	.45
Dinitrotoluene .. lb.	.38 -	.40
Dip oil, 25%, tar acids, car lots, in drums .. gal	.38 -	.40
Diphenylamine (nominal) .. lb.	.80 -	.85
H-acid (nominal) .. lb.	1.65 -	1.70
Meta-phenylenediamine .. lb.	1.25 -	1.30
Monochlorobenzene .. lb.	.18 -	.20
Monothylaniline .. lb.	1.75 -	2.25
Naphthalene crushed, in bbls. (250 lb) .. lb.	.09 -	.09 1/2
Naphthalene, flake .. lb.	.09 1/2 -	.10
Naphthalene, balls .. lb.	.70 -	.75
Naphthionic acid, crude .. lb.	.12 -	.15
Nitrobenzene .. lb.	.40 -	.50
Nitro-naphthalene .. lb.	.18 -	.25
Ortho-aminodiphenol .. lb.	3.20 -	3.75
Ortho-dichlorobenzene .. lb.	.15 -	.20
Ortho-nitro-phenol .. lb.	.75 -	.80
Ortho-nitro-toluene .. lb.	.25 -	.40
Ortho-toluidine .. lb.	.32 -	.35
Para-aminodiphenol, base .. lb.	2.35 -	2.40
Para-aminodiphenol, HCl .. lb.	2.25 -	2.30
Para-dichlorobenzene .. lb.	.10 -	.15
Paranitroniline .. lb.	1.10 -	1.15

Para-nitrotoluene .. lb.	1.25 -	1.40
Para-phenylenediamine .. lb.	2.50 -	2.65
Para-toluidine .. lb.	1.85 -	2.00
Phthalic anhydride .. lb.	.60 -	.70
Phthalic acid, U. S. P., drums (dest.), (240 lb.) .. lb.	2.00 -	12
Pyridine .. gal	2.00 -	3.50
Resorcinol, technical .. lb.	2.90 -	3.00
Resorcinol, pure .. lb.	3.75 -	4.15
Salicylic acid, tech., in bbls. (110 lb.) .. lb.	.35 -	.38
Salicylic acid, U. S. P. .. lb.	.40 -	.45
Salol .. lb.	.85 -	.95
Solvent naphtha, water-white, in drums, 100 gal. .. gal	.30 -	.35
Solvent naphtha, crude, heavy, in drums, 100 gal. .. gal	.19 -	.22
Sulphanilic acid, crude .. lb.	.32 -	.35
Tolidine .. lb.	1.75 -	1.80
Toluidine, mixed .. lb.	.45 -	.55
Toluene, in tank cars .. gal	.35 -	.42
Toluene, in drums .. gal	.41 -	.42
Xylidines, drums, 100 gal. .. lb	.50 -	.65
Xylene, pure, in drums .. gal	.45 -	.47
Xylene, pure, in tank cars .. gal	.45 -	.47
Xylene, commercial, in drums, 100 gal. .. gal	.37 -	.38
Xylene, commercial, in tank cars .. gal	.30 -	.38

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark .. lb.	\$0.31 -	\$0.33
Beeswax, refined, light .. lb.	.34 -	.37
Beeswax, white pure .. lb.	.55 -	.60
Carnauba, No. 1, (nominal) .. lb.	.80 -	.90
Carnauba, No. 2, regular (nominal) .. lb.	.70 -	.80
Carnauba, No. 3, North Country .. lb.	.25 -	.26
Japan .. lb.	.19 -	.20
Mountain, crude .. lb.	.12 -	.14
Paraffine waxes, crude match wax (white) 105-110 m.p. .. lb.	.08 -	.08 1/2
Paraffine waxes, crude, scale 124-126 m.p. .. lb.	.08 -	.08 1/2
Paraffine waxes, refined, 118-120 m.p. .. lb.	.09 -	.09 1/2
Paraffine waxes, refined, 125 m.p. .. lb.	.09 -	.09 1/2
Paraffine waxes, refined, 128-130 m.p. .. lb.	.10 -	.11
Paraffine waxes, refined, 133-135 m.p. .. lb.	.13 -	.14
Paraffine waxes, refined, 135-137 m.p. .. lb.	.14 -	.15
Stearic acid, single pressed .. lb.	.17 -	.17 1/2
Stearic acid, double pressed .. lb.	.18 -	.19
Stearic acid, triple pressed .. lb.	.22 -	.23

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940 .. gal.	\$1.90
Pine oil, pure, dest. dist. .. gal.	1.50
Pine tar oil, ref., sp. gr. 1.025-1.035 .. gal.	.48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla. .. gal.	.35
Pine tar oil, double ref., sp. gr. 0.965-0.990 .. gal.	.75
Pine tar, ref., thin, sp. gr. 1.080-1.060 .. gal.	.36
Turpentine, crude, sp. gr. 0.900-0.970 .. gal.	1.25
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990 .. gal.	.35
Pine wood creosote, ref. .. gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B D, bbl. .. 280 lb.	\$11.75
Rosin E-L .. 280 lb.	11.75
Rosin K-N .. 280 lb.	11.75
Rosin W, G-W, W .. 280 lb.	12.00
Wood rosin, bbl. .. 280 lb.	11.00
Spirits of turpentine .. gal.	1.10
Wood turpentine, steam dist. .. gal.	1.08
Wood turpentine, dest. dist. .. gal.	1.02
Pine tar pitch, bbl. .. 200 lb.	8.50
Tar, kiln burned, bbl. (500 lb) .. bbl.	15.00
Retort tar, bbl. .. 500 lb.	15.00
Rosin oil, first run .. gal.	.70
Rosin oil, second run .. gal.	.73
Rosin oil, third run .. gal.	.90

Solvents

73-76 deg., steel bbls. (85 lb) .. gal.	\$0.41
70-72 deg., steel bbls. (85 lb) .. gal.	.39
68-70 deg., steel bbls. (85 lb) .. gal.	.38
V. M. and P. naphtha, steel bbls. (85 lb.) .. gal.	.30

Crude Rubber

Para-U-priver fine (nominal) .. lb.	\$0.22 -	\$0.23
U-priver coarse (nominal) .. lb.	.15 -	.16
U-priver caucho ball (nominal) .. lb.	.16 1/2 -	.17 1/2
Plantation—First latex crepe .. lb.	.19 -	
Flibbed smoked sheets .. lb.	.18 -	
Brown crepe, thin, clean .. lb.	.16 -	
Amber crepe No. 1 .. lb.	.17 -	

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls. .. lb.	\$0.14 -	\$0.15
Castor oil, AA, in bbls. .. lb.	.15 -	.16 1/2
China wood oil, in bbls. (f.o.b. Pac. coast) .. lb.	.13 -	.14
Cocoonut oil, Ceylon grade, in bbls. .. lb.	.14 -	.14 1/2
Cocoonut oil, Ceylon grade, in bbls. (nominal) .. lb.	.15 -	.16 1/2
Corn oil, crude, in bbls. .. lb.	.11 -	.11 1/2
Cottonseed oil, crude (f.o.b. mill) .. lb.	.08 -	.08 1/2
Cottonseed oil, summer yellow .. lb.	.10 -	.11
Cottonseed oil, winter yellow .. lb.	.13 -	.14
Linseed oil, raw, car lots (domestic) .. gal.	.85 -	
Linseed oil, raw, tank cars (domestic) .. gal.	.80 -	
Linseed oil, boiled, car lots (domestic) .. gal.	.87 -	

Olive oil, commercial.....	gal.	2.75	—	3.00
Palm, Lagos.....	lb.	.07	—	.09
Palm, Niger.....	lb.	.09	—	.09
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.08	—	.09
Peanut oil, refined, in bbls.....	lb.	.15	—	.15
Rapeseed oil, refined in bbls.....	gal.	1.15	—	1.20
Rapeseed oil, blown, in bbls.....	gal.	1.25	—	1.35
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.11	—	.11
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.08	—	.08

FISH

Light pressed Menhaden.....	gal.	\$0.65	—	\$0.70
Yellow bleached Menhaden.....	gal.	.67	—	.70
White bleached Menhaden.....	gal.	.72	—	.75
Blown Menhaden.....	gal.	1.05	—	1.10

Miscellaneous Materials

All f. o. b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.	net ton	\$24.00	—	\$30.00
Barytes, ground, off color, f.o.b. Kings Creek	net ton	22.00	—	26.00
Barytes, crude, 88% to 94% ba., Kings Creek	net ton	10.00	—	12.00
Barytes, floated, f.o.b. St. Louis.....	net ton	26.50	—	28.00
Barytes, crude, first grade, Missouri.....	net ton	10.00	—	12.00
Blanc fixe, dry.....	lb.	.05	—	.05
Blanc fixe, pulp.....	net ton	60.00	—	65.00
Caseine.....	lb.	.14	—	.18
Chalk, domestic, extra light.....	lb.	.05	—	.06
Chalk, domestic, light.....	lb.	.04	—	.05
Chalk, domestic, heavy.....	lb.	.04	—	.05
Chalk, English, extra light.....	lb.	.05	—	.07
Chalk, English, light.....	lb.	.05	—	.06
Chalk, English, dense.....	lb.	.04	—	.05
China clay, (kaolin) crude, f.o.b. mines, Georgia	net ton	9.00	—	12.00
China clay (kaolin) washed, f.o.b. Georgia.....	net ton	12.00	—	15.00
China clay (kaolin) powdered, f.o.b. Georgia.....	net ton	18.00	—	22.00
China clay (kaolin) crude f.o.b. Virginia points	net ton	8.00	—	12.00
China clay (kaolin) ground, f.o.b. Virginia points	net ton	15.00	—	40.00
China clay (kaolin), imported, lump.....	net ton	25.00	—	35.00
China clay (kaolin), imported, powdered.....	net ton	30.00	—	35.00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	gross ton	8.00	—	14.00
Feldspar, crude, f.o.b. Maine.....	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine.....	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. Baltimore.....	net ton	27.00	—	30.00
Fuller's Earth, f.o.b. New York.....	net ton	18.00	—	18.00
Fuller's earth, granular, f.o.b. Fla.....	net ton	25.00	—	25.00
Fuller's earth, powdered, f.o.b. Fla.....	net ton	18.00	—	18.00
Fuller's earth, imported, powdered.....	net ton	35.00	—	40.00
Graphite, crucible, 90% carbon, Ashland, Ala.	lb.	.07	—	.09
Graphite, crucible, 85% carbon, Ashland, Ala.	lb.	.07	—	.09
Graphite, higher lubricating grades.....	lb.	.11	—	.40
Pumice stone, imported, lump.....	lb.	.04	—	.50
Pumice stone, domestic, lump.....	lb.	.06	—
Pumice stone, ground.....	lb.	.04	—	.07
Quartz (acid tower) fist to head, f.o.b. Baltimore	net ton	—	10.00
Quartz (acid tower) 1 1/2 to 2 in., f.o.b. Baltimore	net ton	—	14.00
Quartz (acid tower) rice, f.o.b. Baltimore.....	net ton	—	17.00
Quartz, lump, f.o.b. North Carolina.....	net ton	5.00	—	7.50
Shells, orange fine.....	lb.	1.00	—	1.05
Shells, orange superfine.....	lb.	1.05	—	1.10
Shells, A. C. garnet.....	lb.	.90	—	.95
Shells, T. N.....	lb.	.85	—	.95
Soapstone.....	ton	15.00	—	25.00
Sodium Chloride.....	long ton	—	17.50
Talc, paper making grades, f.o.b. Vermont.....	ton	12.00	—	22.00
Talc, roofing grades, f.o.b. Vermont.....	ton	9.50	—	15.00
Talc, rubber grades, f.o.b. Vermont.....	ton	12.00	—	18.00
Talc, powdered, Southern, f.o.b. cars.....	ton	12.00	—	15.00
Talc, imported.....	ton	60.00	—	70.00
Talc, California Talcum Powder grade.....	ton	20.00	—	45.00

Refractories

Bauxite brick, 56% Al, f.o.b. Pittsburgh	1,000	160	—	160
Chrome brick, f.o.b. Eastern shipping points	net ton	100	—	110
Chrome cement, 40-45% Cr ₂ O ₃	net ton	55-60	—	55-60
Chrome cement, 40-45% Cr ₂ O ₃ , sacks, in our lots, f.o.b. Eastern shipping points	net ton	60-65	—	60-65
Fire clay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works	1,000	55	—	60
Fire clay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works	1,000	45-50	—	45-50
Magnesite brick, 9-in. straight	net ton	110	—	110
Magnesite brick, 9-in. arches, wedges and keys	net ton	121	—	121
Magnesite brick, soaps and splits	net ton	134	—	134
Silica brick, 9-in. sizes, f.o.b. Chicago district	1,000	65-70	—	65-70
Silica brick, 9-in. sizes, f.o.b. Birmingham district	1,000	56-61	—	56-61
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa.	1,000	55-60	—	55-60

Ferro-Alloys

All f.o.b. Works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	\$200.00	—	\$225.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon, carlots.....	lb.	.18	—	.19
Ferro-chrome, per lb. of Cr. contained, 4-6% carbon, carlots.....	lb.	.17	—	.18
Ferro-manganese, 76-80% Mn, domestic.....	gross ton	170.00	—	175.00
Ferro-manganese, 76-80% Mn, English.....	gross ton	165.00	—	170.00
Spiegelisen, 18-22% Mn.....	gross ton	75.80	—	80.00
Ferro-molybdenum, 50-60% Mo, per lb. of Mo.....	lb.	2.00	—	2.50
Ferro-silicon, 10-15%.....	gross ton	60.00	—	65.00
Ferro-silicon, 50%.....	gross ton	80.00	—	85.00
Ferro-silicon, 75%.....	gross ton	—	160.00
Ferro-tungsten, 70-80%, per lb. of contained W.....	lb.	.75	—	.90
Ferro-uranium, 35-50% of U, per lb. of U content	lb.	7.00	—	7.00
Ferro-vanadium, 30-40% per lb. of contained V.....	lb.	6.50	—	7.50

Ores and Semi-finished Products

All f.o.b. New York, Unless Otherwise Stated

Bauxite, 52% Al content, less than 2% Fe ₂ O ₃ , up to 20% silica, not more than 14% moisture	gross ton	\$10.00	—	\$11.00
Chrome ore, Calif. concentrates, 50% min. Cr ₂ O ₃	unit	20	—	7
Chrome ore, 50% Cr ₂ O ₃ , f.o.b. Atlantic seaboard	unit	65	—	7
Coke, foundry, f.o.b. ovens.....	net ton	10.00	—	12.00
Coke, furnace, f.o.b. ovens.....	net ton	8.00	—	10.00
Coke, petroleum, refinery, Atlantic Seaboard.....	net ton	24.00	—	26.00
Fluor spar, lump, f.o.b. Tonuco, New Mexico.....	net ton	17.50	—
Fluor spar, standard, domestic washed gravel Kentucky and Illinois mines.....	net ton	25.00	—	27.50
Ilmenite, 52% TiO ₂ , per lb. ore.....	lb.	.01	—	.01
Manganese Ore, 50% Mn, e. i. f. Atlantic seaport	unit	—	50
Manganese ore, chemical (MnO ₂).....	gross ton	60.00	—	70.00
Molybdenite, 85% MoS ₂ , per lb. of MoS ₂ , N. Y.	lb.	65	—	70
Mazate, per unit of TiO ₂ , e. i. f. Atlantic seaport	unit	35.00	—
Pyrites, Spanish, fines, e. i. f. Atlantic seaport	unit	12	—
Pyrites, Spanish, furnace size, e. i. f. Atlantic seaport	unit	17	—
Pyrites, domestic, fines, f.o.b. mines, Ga.	unit	12	—	14
Rutile, 95% TiO ₂ per lb. ore.....	lb.	.15	—
Tungsten, Scheelite, 60% WO ₃ and over, per unit of WO ₃ (nominal).....	unit	6.00	—
Tungsten, Wolframite, 60% WO ₃ and over, per unit of WO ₃ , N. Y. C.	unit	4.50	—	5.00
Uranium Ore (Carnotite) per lb. of U ₃ O ₈	lb.	2.75	—	3.00
Uranium oxide, 96% per lb. contained U ₃ O ₈	lb.	12.00	—	14.00
Vanadium pentoxide, 99%.....	lb.	2.00	—
Vanadium Ore, per lb. of V ₂ O ₅ contained.....	lb.	.05	—
Zircon, washed, iron free.....	lb.	—

Non-Ferrous Metals

New York Markets

	Cents per lb.
Copper, electrolytic.....	15 75
Aluminum, 98 to 99 per cent.....	38 75
Antimony, wholesale lots, Chinese and Japanese.....	6.12 to 6.25
Nickel, ordinary (ingot).....	45 00
Nickel, electrolytic.....	45.00
Tin, 5-ton lots.....	39.00
Lead, New York, spot.....	7 25

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

California

PASADENA—Throop College of Technology, East California St., has awarded the contract for the construction of a 1-story laboratory to W. C. Crowell, Chamber of Commerce. Estimated cost, \$150,000.

WATTS—The city plans to construct a sewage disposal plant. Koebig & Koebig, 341 Fire Insurance Bldg., Los Angeles, consult engs.

Colorado

DENVER—The State Bd. of Regents plans to build a hospital and laboratory for the curable insane. Bonds were authorized last election Nov. 2 for the construction.

WELLINGTON—The Du Pont Sugar Co., 627 19th St., Denver, will soon award the contract for the construction of a sugar factory. Estimated cost, \$1,000,000. Schwartz Eng. Co., 310 Mack Bldg., Denver, engr.

Illinois

CHICAGO—The Union Stock Yards Casting Co., 231 West 19th Pl., is having plans prepared for the construction of a 1- and 2-story, 60x125-ft. foundry at 4813 South Morgan St. Estimated cost, \$28,000. O. Ritter, 110 South Dearborn St., archit.

WAUKESHA—The city plans to construct a filtration plant, pumping station and intake. Estimated cost, \$600,000. Hood & Becker, engr.

Iowa

AMES—The city will receive bids in February for the construction of a sewage disposal plant, etc. Estimated cost, \$125,000. P. F. Hopkins, engr.

Kansas

TOPEKA—The city is having plans prepared for the construction of a filtration and softening plant using the Kansas River water. Estimated cost, \$735,000. Black & Veatch, Mutual Bldg., Kansas City, Mo., engs. Noted Oct. 6.

Maryland

BALTIMORE—The Baltimore Mfg. Co., manufacturer of chemicals, vinegar, yeast, etc., controlled by the Fleischmann Co., Perry and Plum Sts., Cincinnati, O., plans to construct additions to its 2 plants on Buren and Monument Sts. and Central Ave. and Bank St. Estimated cost, \$1,000,000.

Minnesota

ST. PAUL—The city voted \$3,000,000 bonds to enlarge water plant, including filter plant, etc. Oscar Claussen, City Hall, engr.

Missouri

ST. LOUIS—The Perfection Mfg. Co., Montgomery and Leddingwell Sts., will build a 1-story, 60x60-ft. enameling plant at 2701 Leddingwell St. Estimated cost, \$7,000. Work will be done by day labor.

New York

HADLEY—The No Era Paper Co. has awarded the contract for the construction of an addition and alterations to the machine shop to the H. P. Cummings Constr. Co., 11 Prospect St., Ware, Mass. Estimated cost, \$100,000.

LONG ISLAND CITY—James H. Rhodes & Co., 115 Fulton St., New York City, has awarded the contract for the construction of a factory for the manufacture of abrasives and polishing materials to the Guarantee Constr. Co., 110 Cedar St., New York City. Estimated cost, \$200,000.

ROCHESTER—The Bartholmew Brewing Co., 555 St. Paul St., is in the market for \$100,000 worth of machinery for crude oil refining.

Ohio

ELYRIA—The Lakeshore Rubber Co., 731 Natl. City Bldg., Cleveland, has awarded the contract for the construction of a 2-story factory, to the Donnelly Constr. Co., Lorain. Estimated cost, \$150,000.

WARREN—Brier Hill Steel Co., Youngstown, has taken an option on a 480-acre site for the purpose of constructing a steel mill. Estimated cost, \$1,500,000. E. L. Ford, chm. of the Advisory Com.

Oklahoma

VINITA—The city voted \$160,000 bonds to construct 2 dams, purification plant, etc. H. C. Olmsted, 417 Oil Exch., Oklahoma City, engr.

Pennsylvania

PHILADELPHIA—The L. Martin Co., Milnor St. south of Bleigh St., will build a 1-story, 27x17x55-ft. addition to its lamp-black factory. Estimated cost, \$25,000. Work will be done by day labor.

PHILADELPHIA—The Westmoreland Color & Chemical Co., 22d and Allegheny Sts., has awarded the contract for the altering its present factory, to McNeil Valentine, 811 North Broad St. Estimated cost, \$10,000.

Texas

CORPUS CHRISTI—W. A. Chambers will build an oil refinery to have a daily capacity of 1,500 bbl. of refined oil and gasoline. Estimated cost, \$100,000. Work will be done by day labor.

Wisconsin

AMHERST—The Bd. Educ. is having preliminary plans prepared for the construction of a 3- or 4-story, 60x150-ft. high school on North Main St. A chemical and physical laboratory will be installed in same. Estimated cost, \$200,000. W. C. Alban, Endicott Bldg., St. Paul, Minn., archit.

APPLETON—The Fox River Paper Co. has awarded the contract for the construction of a 2-story, 26x165-ft. paper mill to the Appleton Constr. Co.

FOND DU LAC—The Fond du Lac Paper Co., 298 Forest Ave., is having plans prepared for the construction of a 1- and 2-story, 100x300-ft. paper board factory. E. Steposki, 111 Marquette St., archit. Noted Nov. 3.

FREDERICK—The Bd. Educ., Lynn Bldg., is having plans prepared for the construction of a 2-story, 100x175-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$140,000. E. J. Hancock, Eau Claire, archit. and engr.

GRANVILLE—The T. J. Moss Tie Co., Security Bldg., St. Louis, Mo., plans to construct a tie treating plant, including 3 steel buildings. Estimated cost, \$100,000. J. S. Penney, engr.

JEFFERSON—The Jefferson Rubber Co. is building a 1-story, 80x320-ft. tire factory on Main St. Estimated cost, \$100,000.

WEBSTER—The Bd. Educ. is having plans prepared for the construction of a 2-story, 160x175-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$175,000. E. J. Hancock, Eau Claire, archit. and engr.

New Brunswick

BEAR RIVER—The Clarke Bros., Ltd., will receive bids until Jan. 15 for the construction of a paper mill. Estimated cost, \$100,000.

New Foundland

BONNE BAY—The St. Lawrence Timber Pulp & Steamship Co., Ltd., plans to build a plant including a sulphite mill.

Ontario

LONDON—E. T. Jenkins, Y. M. C. A., 129 Wellington St., plans to build a Y. M. C. A. building. A chemical purification system for a swimming pool will be installed in same. Estimated cost, \$300,000.

Quebec

MONTREAL—The Royal Duke Refining Co., 157 St. James St., plans to build a plant in East Montreal. Plans include equipment. Estimated cost, \$250,000.

New Publications

THE CASTOR-OIL INDUSTRY, by J. H. Shrader. Bull. 867 issued by the U. S. Department of Agriculture.

ARTHUR D. LITTLE, INC., chemist and engineer, 30 Charles River Road, Cambridge, Mass., announces that a limited number of copies of its monograph on "The Petroleum Outlook" are now available for distribution to bankers, brokers, manufacturers and investors free of charge on application. This work comprises an economic study of "The Petroleum Outlook" with especial reference to American fields, a large map and several charts, arranged for comparative reference, with an illuminating discussion of the status of the numerous oil fields. The text, written in popular style, deals with the geology, production history and apparent state of exhaustion of our petroleum resources and may readily be understood by any intelligent layman. It is an impartial, forceful presentation of the petroleum problem without reference to the companies or interests that own or operate in the respective sections. This is one of the most complete and interesting publications for the lay reader that has been issued upon this subject.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1920 meeting Dec. 27, 1920, to Jan. 1, 1921, at Chicago, Ill.

AMERICAN CERAMIC SOCIETY will hold its annual meeting the week of Feb. 21, 1921, at Columbus, Ohio, with headquarters at the Deschler Hotel.

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29, 1921.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its winter meeting at New Orleans, Dec. 6 to 9. Headquarters will be at the Hotel St. Charles.

AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS 1920 annual meeting will be held in the Engineering Societies Building from Dec. 7 to 10 inclusive.

COMMON BRICK MANUFACTURERS' ASSOCIATION OF AMERICA will hold its annual meeting at the Hotel Pennsylvania, New York City, Jan. 31 to Feb. 4.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at the Statler Restaurant, Newark, N. J., the second Monday of every month.

TAYLOR SOCIETY will hold its annual meeting Dec. 2, 3 and 4 in the Engineering Societies Bldg., New York City. The meeting of Dec. 3 at 8 p.m. will be of special interest to metallurgists. The subject will be "The Long Day in the Steel Industry."

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: Dec. 10, American Chemical Society, joint meeting with Society of Chemical Industry, American Electrochemical Society and Société de Chimie Industrielle; Jan. 7, American Chemical Society; Jan. 11, Society of Chemical Industry, Perkin Medal award; Feb. 11, American Electrochemical Society, joint meeting with Society of Chemical Industry, American Chemical Society and Société de Chimie Industrielle; March 11, American Chemical Society, Nichols Medal award; March 25, Society of Chemical Industry; April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Number 22

American Engineering Council Founded Under Hoover's Direction

IT WOULD be difficult to conceive more favorable auspices for the launching of a new organization than those surrounding the first meeting of American Engineering Council. The hearty response given by seven national societies and fourteen local organizations, the latter from eleven different states and the District of Columbia, to the invitation for charter membership can be considered a fair index of widespread interest in the civic duties and opportunities of the engineer. With so many organizations ready to unite for a common purpose, it was doubly fortunate that they were able to find in HERBERT HOOVER a leader who typifies not only the ideals but the achievements of engineers in public service. These two factors—the widespread interest in the movement and the acceptance of leadership by Mr. HOOVER—augur well for the success of American Engineering Council.

It is typical of Mr. HOOVER that he should propose immediately a very definite and tangible work for Council—namely, an investigation of industrial wastes in time, labor, material and money. But it is more than a coincidence that he should have suggested this as its first work. He has long been interested in the subject. He was vice-chairman of the Second Industrial Conference, which made constructive suggestions for new and improved relations between employer and employee. Only recently he was invited to sit in conference with Mr. GOMPERS and other officials of the American Federation of Labor, for the purpose of formulating a program of readjustment on the economic problems now confronting the country. Perhaps it was as a result of that conference that news later emanated from the American Federation of Labor announcing a new attitude toward engineers. Mr. WOLL, vice-president of that organization, is said to have stated: "The viewpoint of the engineer is valuable because it is the viewpoint of a man whose position is such as to enable him to see the whole broad problem involved. He is in a position to know fully the value of being able to realize the creative energy of workers, to bring into play their interest and intelligence."

Here is tangible evidence of the influence of engineering thinking on economic problems and an acceptance by one of the great factors in industry of the soundness of the engineer's viewpoint. We hope that developments will show that American Engineering Council has come into being at an opportune moment, when different elements in industry realize the value of engineering thought and opinion on vital economic problems. A happy conjunction of events points in that direction. A sense of professional solidarity has been aroused. There is work to do and a united disposition to do it.

Psychology of Inflation And Readjustment

IN RETROSPECT, what has occurred in business and industry generally since the Armistice seems natural enough. There was a reaction from war-time conditions. Sellers had been restricted as to prices, either by law, by agreement with the Government or by conscience, and when restrictions disappeared most of them were disposed to secure the highest prices obtainable. Workmen had worked hard during the war and were disposed to relax afterward, endeavoring to get the most money for the least service.

Many men were misled by false logic. In the experience of a generation before the war, activity and prosperity had gone together, and it was inferred that activity meant prosperity. But that was not the case; there was much activity that did not involve real prosperity or progress. The country's experience after the Civil War had been forgotten. For eight years after the Civil War there was great activity, except for a few short periods, but when the panic of 1873 came it was found that there had not been a corresponding degree of prosperity and progress.

For the present, however, our disillusionment has come and the reaction from war-time conditions has spent itself. Men are getting over their spell of endeavoring to do the least work for the most money. These changes are chiefly psychological.

A clear distinction must be made between business conditions that arise from psychological influences and those arising from material influences. In 1908, after the panic of October, 1907, there were some "sunshine clubs" formed. It was preached that the depression was all in men's minds and prosperity could be created by establishing what was called "confidence." The scheme did not work. There was a five-year industrial depression from 1873 to 1878 and another of equal duration from 1893 to 1898. In neither of those periods would it have been possible to make business "good" by men changing their minds. Those depressions were not psychological at all. The country had over-expanded. Facilities had been created that were not needed. Liquid capital had been turned into fixed capital to too great an extent, and the capital could not yield an adequate return.

That is not the condition today. The country has too little railroad facilities. There is not too much capital tied up in railroads, but too little. There are not too many dwelling houses and skyscraper office and hotel buildings, but too few. There is no physical foundation for a business depression. The depression is due to wrong mental attitudes that must be replaced by right ones.

The readjustment, whereby we shall attain an industrial activity that will involve real prosperity and advancement, consists in mental attitudes being

changed. Manufacturers, wholesalers and retailers must become reconciled to receiving smaller profits and working harder for those profits. Labor must bring itself to work harder and more intelligently and be content in many cases with smaller pay in dollars, though the purchasing power of the month's earnings may eventually be increased.

Mass psychology, however, seems endued with a characteristic akin to momentum. Sometimes it swings so far that it swings part way back again. It is quite possible that while everyone is now talking about "readjustment" and predicting that we shall in this readjustment get to a perfectly sound and safe basis, we may after all have another reaction toward inflation from which in turn we shall have to recover. It is doubtful, in other words, whether everything will be "fixed up" to stay.

Ignorance Of Science

IN THESE days when the colleges are being criticised from various points of view and many innovations are being introduced into education, anything that throws light upon the subject should be welcome. One of the most illuminating criticisms of the failings of education is contained in H. G. WELLS' recently published "Outline of History." Mr. WELLS, as is well known, received a scientific education and believes, as HUXLEY did before him, in the need for leavening the old-time classical studies with a considerable proportion of well-taught physical science.

It is in his account of Mr. GLADSTONE that Mr. WELLS assails the old pedantic education that, in spite of its virtues, has so hampered our colleges. Mr. WELLS explains the old-time classical training as consisting mainly of "the study, without any archaeology or historical perspective, of the more rhetorical and 'poetic' of the Latin and Greek classics." The graduates from such a course, continues Mr. WELLS, had no vision of history as a whole, were ignorant of the elementary ideas of biological science, of modern political, social and economic science and modern thought and literature. Such an education as Mr. GLADSTONE'S is typical of that of many of our public men, lawyers and even some business men. Mr. WELLS' test of an education is whether it enables one to interpret correctly the life around him; of Mr. GLADSTONE he says that he never attained any real vision of the world in which he lived.

For instance, "When Mr. GLADSTONE was taken by Sir JOHN LUBBOCK to see CHARLES DARWIN, he talked all the time of Bulgarian politics, and was evidently quite unaware of the real importance of the man he was visiting. DARWIN, Lord MORLEY records, expressed himself deeply sensible of the honor done him by the visit of 'such a great man,' but he offered no comments on the Bulgarian discourse." Obviously this Eton and Oxford graduate, intellectual as he was supposed to be, had little conception of the world-moving importance of DARWIN'S work in science. Therefore, reasons Mr. WELLS, since he could not interpret correctly the life around him, he was not educated.

Again, Mr. GLADSTONE paid a visit to FARADAY, "the English electrician, whose work lives wherever a dynamo spins, who is in the airplane, the deep-sea cable, the lights that light the ways of the world, and wherever electricity serves our kind . . . The man of science tried in vain to explain some simple piece of apparatus

to this fine flower of the parliamentary world. 'But,' said Mr. GLADSTONE, 'after all, what good is it?' 'Why, sir,' said FARADAY, doing his best to bring things home to him, 'presently you will be able to tax it.'" If Mr. GLADSTONE could see the great power-houses and electric lines today, all of which have come from FARADAY'S humble experiments of a century ago, he would see "what good it is"; and he might see also how poorly his education in what Mr. WELLS calls rhetorical literature fitted him to understand the progress of his time.

But Mr. GLADSTONE is not the only prominent man who has failed to do justice to science because of a narrow education. Our own Congress hesitated six years over voting \$30,000 to test MORSE'S telegraph, even after he had demonstrated its merits. When the appropriation was being discussed, one Congressman proposed an amendment that half the money be given for an investigation of mesmerism. When the vote was taken on the original motion, (the amendment having been defeated), it carried by only 89 to 83. MORSE meanwhile had nearly starved to death, after vainly trying to get European nations to buy his invention.

Coming down to the present, it is not difficult to see similar blindness to the importance of science by men trained according to the old classical standards. Congress still votes huge appropriations for more or less useless projects, while cutting to the minimum any sums devoted to engineering or to scientific research. When, occasionally, large amounts are voted for necessary engineering undertakings, men untrained in science are as likely as not to be put in charge. Engineers and technologists employed by the national, state and municipal governments are given as little authority as possible, and are paid salaries astonishingly small compared with what Government-employed lawyers and publicists are paid.

One of the most striking examples of lack of knowledge of science is in our newspapers and general magazines. Reporters with almost no understanding of science are assigned to write accounts of scientific importance, and the way in which they garble the facts and falsehoods they pick up is a disgrace. The apportionment of space in the newspapers further emphasizes the prevailing ignorance of science among men who have received the traditional arts education. Half a page is devoted to a murder or a scandal, or even to a wedding or a society rumor, whereas a tiny paragraph in the lower corner has to do for an important scientific discovery.

It is interesting to observe how ignorant people in general are when a scientific matter is mentioned. Speak in the ordinary club or at a general social gathering some such term as "organic acid" or "fuselage" or "metallurgy," and notice the blank looks that follow. As HERBERT SPENCER pointed out, the customary education that most people receive makes them more anxious to pronounce correctly some word of merely literary significance, such as "Iphigenia" or "Don Quixote" or "L'Allegro," than to understand the scientific phenomena among which they live. Listen to the remarks of the average citizen as a street car passes a bridge under course of construction, or when the composition of the latest anarchist bomb is discussed. In spite of all the books on science available, and all the science courses in our schools and colleges, the average citizen, like the lawyer and the reporter and the public man, is astonishingly ignorant of science and engineering.

Concerning Communism

TO THOSE whose mental make-up is such that they shrink from the increasing intensity of the competitive organization of society, the complete fiasco made in the most colossal communistic experiment of all history--Soviet Russia--must appear as a death-blow to their hopes. To the hypothesis of a possible communistic organization of society there attaches a fascination akin to the search for perpetual motion. Primitive men looked upon the competitive beasts of prey with fear and aversion; but the bee, the example par excellence of communism in the animal world, they regarded with admiration of his energy and efficiency mingled with respect for his powers of self-defense. It is natural, therefore, that throughout the ages men have been attracted by the idea of pooling their resources so that each should contribute what he best could to the common store and each withdraw from it in accordance with his needs.

But the verdict of human experience to date is that, except under special circumstances and to only a limited degree, such an organization simply will not work. To the engineer it is at once evident that there are certain fundamental factors in such a plan. The total amount contributed by the group must exceed the total withdrawn by a factor of safety sufficient to create a reserve that may be drawn upon in periods of heightened consumption or lowered production, otherwise the project will collapse, as it has in Russia.

A close analogy would be with a life insurance association, where the premiums paid in must be sufficient to meet the death payments and create a reserve to tide over periods when payments are unusually heavy. The life insurance problem is not difficult when sufficient actuarial data are available, for the amount of the payments is agreed upon and it remains only to fix the amount of the premiums. But there can be no actuarial data for a communistic society, because "the sky is the limit" for the demands that may be made upon it and there is no means of determining the amount which the individual must contribute. We say must contribute, but pure theoretical communism simply predicates that each shall contribute according to his ability and withdraw according to his needs, in the simple faith that the Providence which looks after three well-known groups (one of which is fast vanishing) will somehow arrange it that there will always be enough for all.

However, every time the experiment is tried there never is enough for all. The reasons why are two--optimism and ambition. Mankind on the average tends to believe that everything will come out all right; the Chinese expression for "tomorrow" is *ming tien*--"bright day." If everything will come out all right "there is no use breaking our necks," "you only live once, you know," and so mankind on the average is a little slack, needing some spur or urge to bring out its full powers. And mankind is ambitious; few there are who have attained the Nirvana of having their desires no greater than their means of gratification and those who have so attained are far above the level of the average. With such material to work upon, the engineer can prophesy the outcome as easily as he can prophesy what will happen when the flow from a reservoir exceeds the input.

Communism cannot work except by the remodeling of human nature.

Trade Secrets and -- Industrial Chemists

SOBER reflection over the thoughts advanced at the Chicago and Milwaukee A.C.S. intersectional meeting detailed elsewhere in this issue leads to the conclusion that much information on chemical processes is now being uselessly suppressed to the retardation of industry. Trade secrets are in a large majority of cases the common property of operators within the trade. The only object in the suppression of such information is to prevent competitors from profiting thereby. But since they are already advised, an open procedure can work no harm. It may do inestimable good to other industries; for it is always true that operation in one industry may be modified for profitable adaptation to work entirely outside the line in which it originates.

There are exceptions to spreading information immediately in the case of patents and certain non-patentable mechanical features. Time is the governing factor, however. The other fellow soon discovers the new development.

A certain manufacturer has very rigid rules regarding secrecy of his operations. He signs up his employees, surrounds his plant with mystery and a high board fence. But the fence is not high enough to hide the heavy niter fumes issuing from the towers of his sulphuric acid plant. Directly across the street is a large set of acid chambers operating at full capacity. Not the slightest mist is apparent over its stack. This plant is operated by a company with a broad open-handed policy that makes for advancement throughout the technical departments. The first company cannot well muster the "brass" to ask to inspect the plant where other folks are welcome. They will probably send a representative in the dark of the night or disguised as a workman to find out how it's done. Meanwhile the fume waves in the prairie breeze like a flag proclaiming ingrown industrial degeneracy to the passing chemist.

When you feel secretive, remember the other fellow may have a better line of information than yourself. Dissemination of information brings returns and is therefore not simply altruistic.

Civil Engineers And the Federation

CORRIDOR gossip at the recent meeting of American Engineering Council in Washington concerned the action of the Civil Engineers in declining by a decisive majority to join the new organization. While regret was expressed that the A. S. C. E. had not seen fit to unite with the other founder societies in the movement for public service, the opinion was frequently ventured that the Civils would yet change their minds and come into the fold. The situation reminded one of that other time when they stood upon their dignity and declined to join the founder societies in accepting Mr. CARNEGIE'S offer of a permanent home. Subsequently, after everybody was settled in the building, they decided to come in.

No fault can be found with the action of the Civil Engineers in declining to join American Engineering Council. One may question, however, whether the Board of Direction of the A. S. C. E. was not exhibiting a petty attitude and a dog-in-the-manger policy when it formally directed its representatives on the present Engineering Council to decline to transfer the activities of that body to American Engineering Council.

First Meeting of American Engineering Council

An Account of the Organizing Sessions at Washington, Nov. 18 to 20—Twenty-one Member-Societies Join the Federation—Herbert Hoover Elected President—Washington Selected as Permanent Headquarters—Investigation of Industrial Wastes Authorized

QUITE fulfilling the expectations of its sponsors, the first meeting of American Engineering Council of the Federated American Engineering Societies, held in Washington, Nov. 18 to 20, was a marked success from the point of view of member-societies represented and official personnel selected to launch the organization. Practically all of the three-day session was consumed with the routine of organization, but did not lack in a number of inspirational addresses interspersed with the more prosaic business of putting the Council's machinery in running order.

Herbert Hoover was elected president by unanimous vote, and Washington, D. C., was chosen as the permanent headquarters of Council.

In response to a suggestion made by Mr. Hoover in his address, the Executive Board indorsed his plan for an investigation of industrial wastes, and authorized him to create an organization for that purpose.

TWENTY-ONE MEMBER SOCIETIES

The first session was called to order by Richard L. Humphrey, chairman of the Joint Conference Committee which was charged at the organizing conference last June with the duty of bringing American Engineering Council into existence in accordance with the provisions then made. In his opening address Mr. Humphrey reviewed the work of the Joint Conference Committee in keeping in active touch with the 116 organizations which had been invited to join the Federated American Engineering Societies. As a result of its labors this first meeting was called to order with 21 member-societies representing an aggregate membership of about 60,000, which is 50 per cent of the aggregate membership of all organizations invited to join. Mr. Humphrey concluded his address with a review of some of the work which American Engineering Council can undertake.

COMPLETE LIST OF CHARTER MEMBER-SOCIETIES

The complete list of charter member-societies and their representatives as of Nov. 20, 1920, is as follows:

Alabama Technical Association, Birmingham, Ala.: Paul Wright.

American Institute of Chemical Engineers, Brooklyn, N. Y.: Harrison E. Howe.

American Institute of Electrical Engineers, New York: Calvert Townley, Comfort A. Adams, A. W. Berresford, H. W. Buck, F. L. Hutchinson, G. A. Waters, William McClellan, L. F. Morehouse, John H. Finney, Charles S. Ruffner, Charles F. Scott, Lewis B. Stillwell.

American Institute of Mining and Metallurgical Engineers, New York: Herbert Hoover, J. Parke Channing, Arthur S. Dwight, Edwin Ludlow, Allen H. Rogers, Philip N. Moore, P. E. Barbour, Joseph W. Richards.

American Society of Agricultural Engineers, Ames, Iowa: Samuel H. McCrory.

American Society of Mechanical Engineers, New York: L. P. Alford, Charles T. Main, Arthur M. Groene, Jr., E. S. Carman, Arthur L. Rice, Dexter S. Kimball, Paul Wright, W. A. Hanley, William B.

Gregory, V. M. Palmer, H. P. Porter, Robert H. Fernald, L. C. Nordmeyer, Fred J. Miller (alternate), Robert Sibley (alternate), Charles Whiting Baker (alternate).

Associated Engineering Societies of St. Louis: William E. Rolfe.

Detroit Engineering Society, Detroit: D. J. Sterrett. *Engineering Association of Nashville, Tenn.*: A. F. Ganier.

Engineering Society of Buffalo, N. Y.: W. B. Powell. *Grand Rapids Engineering Society*, Grand Rapids, Mich.: Burrill A. Parks.

Kansas Engineering Society, Topeka, Kan.: L. B. Smith.

Louisiana Engineering Society, New Orleans, La.: W. B. Gregory.

Mohawk Valley Engineers' Club, Utica, N. Y.: Byron E. White.

Taylor Society: Morris L. Cooke.

Technical Club of Dallas, Tex.: O. H. Koch.

Cleveland Engineering Society: John F. Oberlin.

Engineers' Club of Baltimore, Md.: W. W. Varney.

Society of Industrial Engineers: L. W. Wallace.

Washington Society of Engineers, Washington, D. C.: E. C. Barnard.

York Engineering Society: William J. Fisher, H. A. Delano (alternate).

The following organizations, which are considering membership but have not taken final action, participated in the meeting and sent delegates as indicated:

American Institute of Architects, Washington, D. C.: Percy C. Adams.

American Society of Heating and Ventilating Engineers, New York: Champlain L. Riley.

American Society for Testing Materials, Philadelphia, Pa.: C. D. Young, C. L. Warwick.

Florida Engineering Society, Gainesville, Fla.: L. R. McLain.

Illuminating Engineering Society, New York: Walter C. Allen.

Iowa Engineering Society, Iowa City, Iowa: John H. Dunlap.

National Fire Protection Association, Boston, Mass.: Ira H. Woolson, D. Knickerbacker Boyd.

Society of Automotive Engineers, New York: Howard E. Coffin, David Beecroft, Coker F. Clarkson, H. M. Crane, C. F. Kettering, H. M. Swetland.

Society for the Promotion of Engineering Education, Pittsburgh, Pa.: F. L. Bishop.

Engineering Society of Western Massachusetts: C. L. Newcomb.

ELECTION OF TEMPORARY OFFICERS

Election of temporary officers resulted in the appointment of E. S. Carman, American Society of Mechanical Engineers, temporary chairman, and William E. Rolfe, Associated Engineering Societies of St. Louis, temporary secretary. In accepting the position Mr. Carman acknowledged the honor paid through him to the American Society of Mechanical Engineers, which was the first to accept charter membership in the Federation. He also emphasized public service as the keynote of the organization and meeting.

At this point Philip N. Moore offered a resolution of regret that Richard L. Humphrey and his colleagues of the American Society of Civil Engineers, who had worked so zealously for the success of the Federation, were, by the action of their society, eliminated from

OFFICERS of AMERICAN ENGINEERING COUNCIL of the FEDERATED AMERICAN ENGINEERING SOCIETIES

CALVERT TOWNLEY
AMERICAN INSTITUTE OF ELECTRICAL
ENGINEERS, VICE-PRESIDENT

WM E. ROLFE
ASSOCIATED ENGINEERING SOCIETIES
OF ST. LOUIS, VICE-PRESIDENT

ENGINEERS, VICE-PRESIDENT

J. PARKE CHANNING
AMERICAN INSTITUTE OF MINING AND
METALLURGICAL ENGINEERS, VICE-PRESIDENT

L. W. WALLACE
SOCIETY OF INDUSTRIAL ENGINEERS
TREASURER

further participation in the Federation's affairs. The privilege of the floor was extended to Mr. Humphrey and his associates.

A number of temporary committees were appointed to formulate immediate business of the Council and report at later sessions. Care was taken to apportion membership on these committees among the national, state and local representatives. These committees and their chairmen were as follows: Program, Percy E. Barbour, A. I. M. E.; Credentials, O. H. Koch, Technical Club of Dallas, Tex.; Constitution and By-laws, C. F. Scott, A. I. E. E.; Nominations, W. B. Powell, Engineering Society of Buffalo, N. Y.; Plan and Scope, L. D. Nordmeyer, A. S. M. E.; Budget, Calvert Townley, A. I. E. E.; Resolutions, F. E. Webner, Society of Industrial Engineers.

DETERMINATION OF DISTRICTS AND REPRESENTATION ON EXECUTIVE BOARD

In order to constitute the Executive Board of American Engineering Council as provided in the by-laws it was necessary at this point to consider the division of the United States into districts from which the various members of the Executive Board should be selected.

The constitution provides for an Executive Board of thirty, of whom six shall be officers of the Council and twenty-four selected partly by the national societies, and the remainder by the local, state and regional societies and affiliations according to districts. In view of the fact that new member-societies were likely to join the organization and desire representation on the Executive Board it was suggested by L. P. Alford that only twenty members of the board be selected at this time, fourteen from the national societies and six from the locals. This was readily agreed to, as was also the following division of the United States into six districts: 1, New England and New York; 2, Michigan, Wisconsin and Minnesota; 3, Ohio, Indiana and Illinois; 4, New Jersey, Pennsylvania, Delaware, Maryland and District of Columbia; 5, Southern States below the Potomac and Ohio rivers, with Louisiana and Texas; 6, remaining states west of the Mississippi River.

As finally constituted the Executive Board consists of twenty members apportioned among the national societies and the six districts as follows:

American Institute of Chemical Engineers, 1, Harrison E. Howe.

American Institute of Electrical Engineers, 4, H. W. Buck, William McClellan, Charles F. Scott and Lewis B. Stillwell.

American Institute of Mining and Metallurgical Engineers, 3, Arthur S. Dwight, Edwin Ludlow and Philip N. Moore.

American Society of Agricultural Engineers, 1, Samuel H. McCrory.

American Society of Mechanical Engineers, 4, L. P. Alford, Arthur M. Greene, Jr., E. S. Carman and Fred J. Miller.

Taylor Society, 1, Morris L. Cooke.

District No. 1, one-half each for *Engineering Society of Buffalo*, W. B. Powell, and *Mohawk Valley Engineers' Club*, Byron E. White.

District No. 2, one-half each for *Detroit Engineering Society*, D. J. Sterrett, and *Grand Rapids Engineering Society*, Burritt A. Parks.

District No. 3, 1, *Cleveland Engineering Society*, John F. Oberlin.

District No. 4, 1, *Engineers' Club of Baltimore*, W. W. Varney.

District No. 5, 1, *Technical Club of Dallas*, O. H. Koch.

District No. 6, 1, *Kansas Engineering Society*, Lloyd B. Smith.

In view of the fact that all of the societies which have been invited to join the Federation have not yet been able to reach a decision it was the sense of the meeting that the time for accepting invitation to charter membership should be extended to July 1, 1921, and formal action was taken to that effect.

WASHINGTON CHOSEN AS HEADQUARTERS

Philip N. Moore then brought up the subject of permanent headquarters for American Engineering Council and addressed his remarks particularly to the advantages of Washington, D. C., for this purpose. His suggestion resulted in a lively discussion of the merits and demerits of various locations for headquarters. New York was favored by some on account of its business facilities, while others were favorable to inland cities on account of their central location. In view of the evident time-consuming nature of this discussion and the impossibility of reaching a decision at that session the matter was made a special order of business for the afternoon session. At that time favorable action was taken on Mr. Moore's resolution to the effect that it was the sense of the meeting that headquarters for American Engineering Council should be established in Washington. An amendment to refer the matter to the Executive Board with power to act was lost by a wide margin, though it became incumbent upon the Executive Board later to recognize the sentiment of the Council and formally select Washington as headquarters.

Prior to adjournment of the morning session Mr. Hutchinson, one of the directors of Engineering Societies Service Bureau, New York, told of the work of that organization for the first nine months of 1920. The work of this organization is of interest to American Engineering Council, as the latter is expected to take over its duties. At present the Bureau is expending a total of about \$9,000 per annum, but should have a budget of at least \$15,000 for 1921. In view of increasing unemployment its service is likely to be much needed during the coming winter, and it was felt that the most efficient service possible should be placed at the disposal of the engineering profession.

ADDRESS ON CONSERVATION OF LABOR

The session on Friday morning, Nov. 19, was opened with an address by L. W. Wallace, Society of Industrial Engineers, on "Conservation of Labor." His thesis was that in view of the tremendous loss of labor resulting from the war, as well as the lowered morale consequent upon the general dislocation of business and industry, it was of the utmost importance to increase the potential value of human beings in industrial processes. He mentioned four great factors in accomplishing this end—namely, the safety adviser, the welfare adviser, the industrial medical adviser, and industrial education. He showed statistically the effect of the safety movement in reducing accidents with the consequent loss of time and production. Welfare work, in whatever name it might be undertaken, was, in the speaker's opinion, a failure as long as it was offered as a substitute for wages or other just compensation, but a marked success if undertaken as a conservation measure in the interest of both employer and employee. The industrial medical adviser he found to be an important factor in reducing time lost due to preventable illness. But it was in industrial education that Mr. Wallace

found great hope for the future. Since the trained mind excels the untrained it is of first importance to raise the general level of intelligence of all labor. The object of industrial education should be not so much to make the worker a better machine but to increase his usefulness to society by broadening his mind and developing his intelligence. One of the greatest opportunities of industrial education is to develop intelligent subordinate leaders, foremen, etc. The speaker believed that it was one of the functions of engineers to improve industrial conditions through their recognition of the laws of cause and effect and to devise such means of avoiding industrial waste, and to so administer them that they would accomplish their purpose. He closed his address with a plea for the "industrially handicapped" who now finds it impossible to serve society usefully on account of lack of training. Mr. Wallace was of the opinion that the great loss of labor occasioned by war was making it more and more necessary to make use of individuals handicapped by loss of arms, legs, eyes, etc.

HOOVER CHOSEN AS PRESIDENT

The report of the Committee on Nominations was received with the greatest interest because the result of its deliberations was conceded to be of the most vital importance to the success of Council. In making its report the committee explained that it had endeavored to pick men who were imbued with the spirit of public service, which is the underlying motive of the Federation. It also explained that an effort had been made to distribute representatives fairly among the national and local societies. Keeping these factors in mind, it suggested the following officers:

President: Herbert Hoover.

Vice-presidents for a two-year term: Calvert Townley, American Institute of Electrical Engineers, and William E. Rolfe, Associated Engineering Societies of St. Louis.

Vice-presidents for one-year term: Dexter S. Kimball, American Society of Mechanical Engineers, and J. Parke Channing, American Institute of Mining and Metallurgical Engineers.

Treasurer: L. W. Wallace, Society of Industrial Engineers.

The nominations were accepted and the nominees unanimously elected. Mr. Hoover was immediately escorted to the chair amid loud and prolonged applause, the audience rising in recognition of its approval. Mr. Hoover said that he found it impossible to refuse to accept service where it is of importance to the engineering profession and the country at large. He said he had long been interested in giving the engineer a voice in the community and that there never had been a time when his voice was so much needed as now. In view of the fact that he had an important engagement with the American Red Cross it was necessary for him to be excused. Mr. Townley then took the chair and called upon each of the newly elected officers for a brief talk.

REPORTS OF OTHER COMMITTEES

The Council then proceeded to consideration of the report of the Committee on Constitution and By-laws. The committee based its recommendation on the document prepared by the Joint Conference Committee and adopted by the Organizing Conference on June 4, 1920. A few minor changes were made. In Article VI, relating to funds, the sentence reading "No portion of such funds shall be applied to the use of local affiliations or

state councils" was changed to read "No portion of such funds shall be appropriated for the operating expenses of local affiliations or state councils." It was felt that the original wording would prevent Council from lending active assistance to local bodies where participation might be desired and needed.

Chapter V of the by-laws, on publicity, was the cause of much irrelevant discussion, but was finally allowed to stand as originally written. The constitution and by-laws were then adopted as amended in minor particulars.

The Committee on Plan and Scope suggested a number of matters of public interest to which Council might devote its attention. This report was subsequently revised in conference with Mr. Hoover and considered by the Executive Board. Their action is announced elsewhere in this report.

In reporting for the Budget Committee Mr. Channing said that they had considered a minimum and maximum income, basing the former on the present actual membership of the Federated American Engineering Societies and the latter on a prospective membership. Under the former an annual income of approximately \$59,000 would be available, while the maximum possibility would be \$80,000. The fixed expenses for office and overhead, Service Bureau, meetings, committees, traveling, etc., were estimated to amount to a minimum of \$56,500 which would be well within the estimated income. The report was accepted for guidance of the Council.

At the evening session of Nov. 19 Mr. Hoover delivered an address embodying his conception of the work of American Engineering Council and outlining in some detail the problems which it might consider. His address is published in full elsewhere in this issue. The evening session was followed by an informal reception and smoker tendered by the Engineering Societies of Washington, D. C. This closed the first meeting of American Engineering Council.

MEETING OF EXECUTIVE BOARD

The meeting of the Executive Board was convened at 9 a.m. Nov. 20, with Vice-President Rolfe in the chair and C. F. Scott secretary pro tem. The first matter under consideration was the selection of an executive secretary. In view of the importance of this matter the Board appointed a committee to canvass eligible persons and report back to the Board at its next meeting. This committee consists of Mr. Hoover, ex officio; L. W. Wallace, chairman, Box 588, Baltimore, Md., and Messrs. Townley, Moore, Scott, Oberlin and Alford. The committee will be glad to receive suggestions for executive secretary. The Board formally ratified the selection of Washington as headquarters, but deferred selection of offices until the executive secretary is elected. It also extended until July 1, 1921, the time for acceptance to charter membership by those societies originally invited to join the Federation. In accordance with its principle for full publicity the Board decided to establish means for making available to the daily and technical press and the publications of constituent bodies complete information and news relating to the Federation and Council.

INDORSEMENT OF PLAN TO ESTABLISH DEPARTMENT OF PUBLIC WORKS

The resolution by Mr. Moore recognizing the importance of the movement to secure a federal Department

of Public Works and favoring continuance of efforts to that end brought forth prolonged and earnest discussion, centering chiefly in the question of what kind of support American Engineering Council should give such projects. It was the consensus that Council should not establish the precedent of committing itself to financial support of these movements, but should direct its efforts toward the creation of public sentiment and the preparation of reliable information for dignified and legitimate use. In this connection Mr. Stillwell described the procedure of the French Engineering Council as a medium for expressing the engineer's voice in public affairs. Mr. Moore finally made clear the purport of his resolution and it was adopted.

Discussion of the report of the Committee on Plan and Scope as subsequently modified after conference with Mr. Hoover resulted in the adoption of the following items, which are arranged approximately in the order of their appropriateness and importance:

1. To serve the public interest by investigation and advice to all public governmental and voluntary bodies dealing with national economic problems.

Canada's Pulpwood Laws and Regulations

When the Canadian provinces were confederated into the Dominion of Canada, one of the articles of confederation conferred upon the respective provinces was the sovereignty and control over their own natural resources. The same authority confers upon the Canadian Parliament the sole power to legislate on matters affecting tariffs as to both exports and imports. Regulations have been adopted by Ontario, Quebec and New Brunswick which require that pulpwood cut from the Crown lands in these provinces must be manufactured into pulp or paper in Canada. These have been summarized by Consul Johnson of Kingston, Ont., in *Commerce Reports*.

An order in council passed Jan. 13, 1900, which was later amended by a law (63 Victoria, chap. 11), requires lumber cut from the Crown lands in Ontario to be manufactured in Canada. It was not until 1902 that this regulation was also applied to pulpwood.

TIMBER LICENSES AT AUCTION

In the Province of Quebec licenses to cut timber on Crown lands are disposed of at public auction. The license thus acquired entitled the holder to "cut timber on ungranted lands of the Crown at such rates and under such restrictions as may from time to time be established by the Lieutenant Governor in council and of which notice shall be given in the *Official Gazette*." Article 1,598 provides that no license shall be granted for longer than twelve months.

Article 1,600 stipulates that "such license shall vest in the holder thereof all rights of property in all trees, timber and lumber cut within the limit of the license during the term thereof, whether cut by authority of the owner of the license or by any other person with or without his consent."

The regulations now in force by virtue of the first-cited article of the law are embodied in an order in council under date of April 26, 1910, revoking all previous regulations "incompatible with the present" and amended in its turn by an order in council of June 13, 1918.

Other clauses having a bearing on the subject are:

1. All licenses to cut timber are subject to a yearly

2. Department of Public Works.
3. Conservation of natural resources.
4. Co-operation with other national organizations, technical, industrial and commercial.
5. Technical education.
6. Transportation, particularly highways.
7. Advice to state, regional and local societies.
8. National Bureau of Economic Research.
9. Public fire protection.
10. Patents.
11. National Board for Jurisdictional Awards.
12. International affiliation of engineers.
13. State organization of local affiliations.
14. Licensing and local registration of professional engineers.
15. Classification and compensation of engineers.
16. Engineering Societies' service bureau.

In order that the Executive Board might continue functioning until the executive secretary is elected L. P. Alford was elected secretary pro tem. Matters pertinent to Council's affairs may be addressed to him care American Society of Mechanical Engineers, 29 West 39th St., New York City.

The Executive Board then adjourned subject to the call of the president not later than Jan. 31, 1921.

ground rent of \$5 per square mile or fraction of a square mile, dating from the first of September, 1910. They are granted for twelve months, from the first of May to the thirtieth of April, and after their issue no claim shall be admitted for the repayment of any overcharge for ground rent or fire tax due to the incorrect measurement of the area of the limit.

2. Licenses expire on the thirtieth of April following the date of their issue, but the licensee having complied with existing regulations is entitled, up to the first of September following, to a renewal of his license. He shall forfeit such right through any infringement of the law and of the regulations. The Minister of Lands and Forests may, however, permit the renewal of the license on payment of the ground rent and of any other penalty he may be pleased to impose.

Besides increasing the stumpage dues, the amendment adopted in 1918 also raises the ground rent to \$6.50 for the years 1919-20 to 1923-24 and to \$8 for the years 1924-25 to 1928-29, inclusive, and provides that in the case of licensees who do not exploit their limits such ground rent may at any time be augmented, the Crown to determine the quantity of wood to be cut for constituting sufficient exploitation. "Transfers of limits or of divided or undivided portions thereof are effected in writing, subject to the Minister's acceptance and to the payment of a transfer bonus of \$4 for every square mile or fraction of a square mile."

REGULATIONS GOVERNING USE OF TIMBER

Regulations as to the use of timber cut under license were adopted by the Quebec Government on April 26, 1910, which read:

All timber cut on Crown lands after the first of May, 1910, must be manufactured in Canada—that is to say, converted into pulp or paper, deals or boards, or into any other article of trade or merchandise of which such timber is only the raw material. The following shall not be considered as manufactured within the meaning of the regulation: Timber simply cut into lengths, piled, barked, or otherwise worked preliminary to the manufacture of pulp or paper, deals or boards or any other articles of commerce.

New Brunswick passed similar legislation on April 26, 1911. There are no statutes prohibiting or regulating the export of pulpwood from Nova Scotia or British Columbia.

Freehold lands are not subject to the manufacturing clause restrictions, and wood cut on these lands may be exported or handled in any way that the owner sees fit.

Investigation on Pyrolytic Production of Phosphoric Acid

Briquetted Charge of Sand, Coke and Mine Run Hard Rock Phosphate Smelted in a Furnace Fired With Fuel Oil—Phosphoric Anhydride and Water Vapors Condensed in a Cottrell Precipitator, Giving an Acid Solution—Commercial Possibilities Shown

BY WILLIAM H. WAGGAMAN AND THOMAS B. TURLEY

FROM the standpoint of conservation the production of phosphoric acid by smelting mixtures of phosphate rock, sand and coke has always appeared particularly attractive, and since Ross, Carothers and Merz¹ pointed out the advantages and demonstrated the feasibility of collecting the fumes of phosphoric acid by means of the Cottrell precipitator the volatilization method of producing this acid has taken on an added interest. Not only is it possible to treat relatively low-grade phosphates by this method but the product obtained is sufficiently concentrated to admit of the expense of long freight hauls and heavy handling charges.

The furnace process of treating phosphate rock is by no means new, but is based upon the old method of making phosphorus. The scheme was proposed and patented in this country as far back as 1889² and more than twenty patents³ have since been issued on devices and treatments designed to effect the nearly complete evolution of phosphoric acid from phosphate rock mixed with either sand or coke, or both. In most of these patents the arc furnace is the type stipulated as necessary to smelt the phosphatic charge and therefore it is generally believed that the complete volatilization of this acid from such mixtures can be brought about only under the conditions and at the temperatures attained in the electric furnace.

FUEL VERSUS ELECTRIC SMELTING

The commercial feasibility of using the electric furnace for the production of phosphoric acid, however, appears somewhat dubious except where a pure product commanding a high price is desired. For fertilizer purposes pure phosphoric acid is not required and the cost of the product must be relatively low. Assuming that electric power might be available at \$25 per hp.-yr., Carothers⁴ in his report on the electric smelting of phosphates places the cost of P_2O_5 (exclusive of interest charges, taxes and depreciation) at 3.39c. per lb. Waggaman and Wagner⁵ later showed that this cost might be materially reduced by using "mine run" phosphates instead of the more costly washed rock and employing the phosphoric acid produced therefrom to treat a fresh batch of the mineral, obtaining available phosphoric acid in the form of double superphosphate as the final product. But even under the most favorable conditions it is still an open question whether or not phosphoric acid for fertilizer purposes can be produced by the electric-furnace process at a price which will compete with that obtained by the sulphuric-acid method.

Since the electric furnace, however, performs no other function in this process than that of heating the charge to a temperature where phosphorus and phosphoric acid are readily evolved, and is simply a convenient form of apparatus to bring about the decomposition of the phosphate rock under reducing conditions, it seems evident that if these same conditions can be fulfilled by means of fuel in lieu of the electric arc a great saving in the cost of production should be effected.

The writers have found that practically the same results can be obtained at the temperatures attained in a fuel-fed furnace, and in the preliminary report⁶ on this process data were presented showing that the nearly complete evolution of phosphoric acid from a phosphate mineral is perfectly feasible where gas or oil is used as the heating agent, provided reducing conditions are maintained until the mass is brought to a molten condition. From 60 to 98 per cent of phosphoric acid has been driven off from such mixtures by means of fuel in the laboratory, and similar yields were obtained by the use of a furnace holding about 200 lb. of charge. As the process finally developed, however, the furnace used in these larger-scale experiments proved to be poorly designed to handle the charge and the bulk of the slag produced did not show a volatilization of more than 63.2 per cent of P_2O_5 . It was decided, therefore, to continue the work with more suitable equipment and under more favorable conditions.

It is recognized that the final proof of the value of this furnace process must rest in a plant of commercial size, but the funds were not available to construct such a plant, so a furnace of semi-commercial size with the auxiliary equipment for burning the combustible gases and collecting the phosphoric acid evolved was erected at Arlington Farm, Va., with a view to solving some of the numerous chemical and mechanical details involved and obtaining sufficient data to approximate the cost of producing phosphoric acid by this process.

Considerable work yet remains to be done before the best type of furnace and equipment is finally established. Insufficient funds made it necessary to utilize much machinery and material ill adapted to the purpose and this fact, coupled with a very limited personnel, has made the problem a difficult one. The small size of the furnace employed has necessarily caused an enormous loss of heat units through radiation and the relatively short duration of the experimental runs has indicated a higher fuel consumption than would be shown in protracted tests. Nevertheless the results obtained are on the whole quite satisfactory and it is believed that the investigation has been carried to the point where the commercial feasibility of the process has been demonstrated and its ultimate economic success practically assured.

The firebrick furnace used* in these experiments is a combination of the open-hearth and blast-furnace types and is heated by means of two oil burners, one at either end of an elongated slag chamber. This slag chamber is boat shaped and was originally 8 ft. in length, 9 in. in width (inside) at either end (where the oil burners are located) but widening to 20 in. in the center. In the center of the arched roof of this chamber is a circular opening leading up into a shaft or charge chamber 6 ft. in height and having the shape of the usual type of blast furnace. The throat of the chamber where it discharges onto the furnace hearth was 12 in. in diameter and widened out gradually until at the top of the bosh the internal diameter was 2 ft. From here on the walls of the chamber tapered gently till at the top of the shaft the opening is only

center of the furnace. In a larger installation, where adequate funds are available, the furnace would be cooled either by bronze plates inserted in the walls and through which water is kept circulating, or by some other convenient water-cooling device employed in blast-furnace practice. In Figs. 1 and 2 the furnace is shown in the course of construction and Fig. 3 is a view of the completed plant. The furnace proper is at the extreme right in these pictures.

OIL BURNERS AND OIL SUPPLY

The oil burners finally adopted for this furnace are manufactured by the Lalor Fuel Oil System Co., of Baltimore, Md. They operate with high-pressure oil (from 50 to 250 lb.), but use air at a relatively low pressure (4 to 8 oz.). The consumption of oil is con-

FIGS. 1 AND 2. PROGRESS VIEWS OF CONSTRUCTION OF FURNACE

FIG. 3. COMPLETED FURNACE

4. CONNECTION AT STOVES WHERE COMBUSTIBLE GASES FROM FURNACE ARE BURNED

14 in. in diameter. This chamber holds a total briquetted charge of 700 lb. One foot from the top of the furnace shaft is a 6-in. flue leading into the dust chamber. The walls of the furnace and slag chamber range from 13½ to 18 in. in thickness and were originally constructed entirely of firebrick.

After several preliminary runs with this furnace it was deemed wise to increase the length of the slag chamber in order to give the oil flame a better chance for combustion. Accordingly the furnace was extended 2 ft. at either end, giving a total length of 12 ft. It was also found that the heat attained was so close to the melting point of firebrick that it was necessary to replace them in part by carborundum brick, which stand satisfactorily the temperatures attained in the

trolled by the pressure and also by the size of the opening in the tips used. These burners have proved eminently satisfactory as long as the oil fed to them is thoroughly filtered. In order to prevent the ends of the burners from melting or getting too hot they are surrounded by steel water jackets set into each end of the furnace at an angle of about 60 deg. from the horizontal so that the oil flame plays upon the furnace hearth. These burners were designed to be placed several inches from the furnace opening and in addition to operating on the air furnished by a volume blower also utilize for combustion the air drawn in around the furnace opening. In this type of furnace, however, the air required to burn the fuel was pre-heated and entirely supplied through the air main from

the volume blowers. The burners operated very satisfactorily under these conditions.

A steel tank holding 500 gal. is used as the main reservoir for the fuel oil and this is connected with a small 80-gal. tank provided with a gage to measure the oil consumption. The oil is fed by gravity to a pump which forces it to the burners under a pressure of from 50 to 200 lb. The oil tanks are shown in Fig. 7.

DUST CATCHER

The dust catcher into which the gases and fumes from the furnace pass was originally designed to act also as a preheater for the air supplying the oil burners and has an annular space surrounding the gas chamber. The use of the dust catcher, however, as a preheater was early abandoned because of the impracticability of rendering the wall between the air and gas chambers air-tight. A bleeder is located in the flue leading from the dust catcher to the stoves where samples of the furnace gases are withdrawn for analysis from time to time during a run.

STOVES

From the dust catcher the gases are led through sliding valves into the stoves, which are three in number. These stoves were intended, first, to burn the combustible gases evolved from the furnace, and second, to absorb the heat units thus produced by means of brick checkerwork; the heat thus absorbed being returned to the system by passing the air required for the oil burners through the heated checkers. The three stoves, however, were built together with a view to reducing radiation losses, and here also it was found impossible to render the common walls sufficiently tight to prevent the gases in one stove from mixing with the air passing through the adjoining one. The likelihood of thus causing an explosion rendered it necessary to abandon them as a means of heating the air to the oil burners. They are used, therefore, only to burn the combustible gases evolved from the furnace. From the stoves the gases are led through a 6-in. brick flue 25 ft. in length to the Cottrell electric precipitator, where the acid is collected. A monel metal exhaust fan placed in this flue serves to withdraw the gases from the furnace and discharge them into the precipitator pipes. The stoves are shown on the extreme left in Figs. 1 and 2, and in Fig. 4 the air and gas connections to the stoves can be seen.

ELECTRIC PRECIPITATOR

The electric precipitator used in this work was designed and built to handle the phosphoric acid evolved from an electric furnace. The electrical equipment has already been described by Ross, Carothers and Merz,¹ but the precipitator proper consists of six 6-in. terra cotta pipes, 12 ft. in length, under which is a stone basin to receive the acid dripping therefrom. The gases enter the precipitator through a 6-in. opening below this basin. Since this electric treater has been erected four years, several of the terra cotta pipes are now considerably out of plumb, making it impossible to center the wires hung in them. Much trouble was encountered due to the current arcing across to the sides of the pipes when a high voltage was employed. Not only is this precipitator located too far from the furnace but its capacity is too low to handle the

quantity of phosphoric acid at the velocity with which it is evolved and discharged into the system. The precipitator proper is shown in Fig. 6 and the electrical equipment in Fig. 8.

AIR SUPPLY AND PREHEATER
